Parseval's Integral

The Poisson integral with $n = 0$,

$$J_0(z) = \frac{1}{\left[\Gamma\left(n + \frac{1}{2}\right)\right]^2} \int_0^\pi \cos(z \cos\theta)\, d\theta,$$

where $J_0(z)$ is a Bessel function of the first kind and $\Gamma(x)$ is a gamma function.

Parseval's Relation

Let $F(\nu)$ and $G(\nu)$ be the Fourier transforms of $f(t)$ and $g(t)$, respectively. Then

$$\begin{aligned}\int_{-\infty}^{\infty} f(t)\bar{g}(t)\, dt &= \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} F(\nu)e^{-2\pi i\nu t}\, d\nu\right]\left[\int_{-\infty}^{\infty} \bar{G}(\nu')e^{2\pi i\nu' t}\, d\nu'\right] dt \\ &= \int_{-\infty}^{\infty} F(\nu) \int_{-\infty}^{\infty} \bar{G}(\nu')\left[\int_{-\infty}^{\infty} e^{2\pi i t(\nu'-\nu)}\, dt\right] d\nu'\, d\nu \\ &= \int_{-\infty}^{\infty} F(\nu)\left[\int_{-\infty}^{\infty} \bar{G}(\nu')\delta(\nu'-\nu)\, d\nu'\right] d\nu \\ &= \int_{-\infty}^{\infty} F(\nu)\bar{G}(\nu)\, d\nu,\end{aligned}$$

where $\bar{z}$ denotes the complex conjugate.

See also Fourier Transform, Parseval's Theorem

References

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, p. 425, 1985.

Parseval's Theorem

Let $E(t)$ be a continuous function and $E(t)$ and E_ν be Fourier transform pairs so that

$$E(t) \equiv \int_{-\infty}^{\infty} E_\nu e^{-2\pi i\nu t}\, d\nu \qquad (1)$$

$$\bar{E}(t) \equiv \int_{-\infty}^{\infty} \bar{E}_{\nu'} e^{2\pi i\nu' t}\, d\nu', \qquad (2)$$

where $\bar{z}$ denotes the complex conjugate. Then

$$\begin{aligned}\int_{-\infty}^{\infty} |E(t)|^2\, dt &= \int_{-\infty}^{\infty} E(t)\bar{E}(t)\, dt \\ &= \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} E_\nu e^{-2\pi i\nu t}\, d\nu \int_{-\infty}^{\infty} \bar{E}_{\nu'} e^{2\pi i\nu' t}\, d\nu'\right] dt \\ &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} E_\nu \bar{E}_{\nu'} e^{2\pi i t(\nu'-\nu)}\, d\nu\, d\nu'\, dt \\ &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} E_\nu \bar{E}_{\nu'} e^{2\pi i t(\nu'-\nu)}\, dt\, d\nu\, d\nu' \\ &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \delta(\nu'-\nu)\, E_\nu \bar{E}_{\nu'}\, d\nu\, d\nu' \\ &= \int_{-\infty}^{\infty} E_\nu \bar{E}_{\nu'}\, d\nu = \int_{-\infty}^{\infty} |E_\nu|^2\, d\nu. \qquad (3)\end{aligned}$$

where $\delta(x - x_0)$ is the delta function.

For finite Fourier transform pairs h_k and H_n,

$$\sum_{k=0}^{N-1} |h_k|^2 = \frac{1}{N} \sum_{n=0}^{N-1} |H_n|^2. \qquad (4)$$

If a function has a Fourier series given by

$$f(x) = \tfrac{1}{2} a_0 + \sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx), \qquad (5)$$

then Bessel's inequality becomes an equality known as Parseval's theorem. From (5),

$$\begin{aligned}[f(x)]^2 = \tfrac{1}{4} a_0^2 + a_0 \sum_{n=1}^{\infty} [a_n \cos(nx) + b_n \sin(nx)] \\ + \sum_{n=1}^{\infty}\sum_{m=1}^{\infty} [a_n a_m \cos(nx)\cos(mx) \\ + a_n b_m \cos(nx)\sin(mx) \\ + a_m b_n \sin(nx)\cos(mx) \\ + b_n b_m \sin(nx)\sin(mx)]. \qquad (6)\end{aligned}$$

Integrating

$$\begin{aligned}\int_{-\pi}^{\pi} [f(x)]^2\, dx &= \tfrac{1}{4} a_0^2 \int_{-\pi}^{\pi} dx \\ &+ a_0 \int_{-\pi}^{\pi} \sum_{n=1}^{\infty} [a_n \cos(nx) + b_n \sin(nx)]\, dx \\ &+ \int_{-\pi}^{\pi} \sum_{n=1}^{\infty}\sum_{m=1}^{\infty} [a_n a_m \cos(nx)\cos(mx) \\ &+ a_n b_m \cos(nx)\sin(mx) + a_m b_n \sin(nx)\cos(mx) \\ &+ b_n b_m \sin(nx)\sin(mx)]\, dx = \tfrac{1}{4} a_0^2 (2\pi) + 0\end{aligned}$$

$$+\sum_{n=1}^{\infty}\sum_{m=1}^{\infty}[a_n a_m \pi\delta_{nm}+0+0+b_n b_m \pi\delta_{nm}], \tag{7}$$

so

$$\frac{1}{\pi}\int_{-\pi}^{\pi}[f(x)]^2\,dx=\tfrac{1}{2}a_0^2+\sum_{n=1}^{\infty}(a_n^2+b_n^2). \tag{8}$$

For a generalized FOURIER SERIES with a COMPLETE BASIS $\{\phi_i\}_{i=1}^{\infty}$, an analogous relationship holds. For a COMPLEX FOURIER SERIES,

$$\frac{1}{2\pi}\int_{-\pi}^{\pi}|f(x)|^2\,dx=\sum_{n=-\infty}^{\infty}|a_n|^2. \tag{9}$$

Bear, H. S. "Part Metric and Hyperbolic Metric." *Amer. Math. Monthly* **98**, 109–123, 1991.

Partial Derivative

Partial derivatives are defined as derivatives of a function of multiple variables when all but the variable of interest are held fixed during the differentiation.

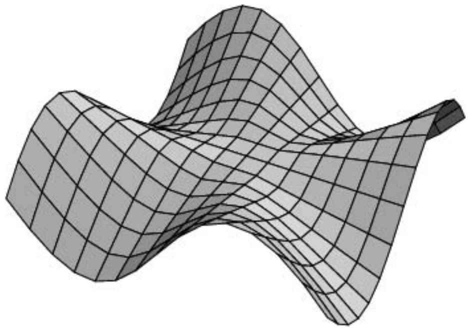
$$\frac{\partial f}{\partial x_m}\equiv \lim_{h\to 0}\frac{f(x_1,\ \ldots,\ x_m+h,\ \ldots,\ x_n)-f(x_1,\ \ldots,\ x_m,\ \ldots,\ x_n)}{h}. \tag{1}$$

The above partial derivative is sometimes denoted f_{x_m} for brevity. For a "nice" 2-D function $f(x,\ y)$ (i.e., one for which $f, f_x, f_y, f_{xy}, f_{yx}$ exist and are continuous in a NEIGHBORHOOD $(a,\ b)$), then $f_{xy}(a,\ b)=f_{yx}(a,\ b)$. Partial derivatives involving more than one variable are called MIXED PARTIAL DERIVATIVES.

For nice functions, mixed partial derivatives must be equal regardless of the order in which the differentiation is performed so, for example,

$$f_{xy}=f_{yx} \tag{2}$$

$$f_{xxy}=f_{xyx}=f_{yxx}. \tag{3}$$



For an EXACT DIFFERENTIAL,

$$df=\left(\frac{\partial f}{\partial x}\right)_y dx+\left(\frac{\partial f}{\partial y}\right)_x dy, \tag{4}$$

so

$$\left(\frac{\partial y}{\partial x}\right)_f=-\frac{\left(\frac{\partial f}{\partial x}\right)_y}{\left(\frac{\partial f}{\partial y}\right)_x}. \tag{5}$$

A differential equation expressing one or more quantities in terms of partial derivatives is called a PARTIAL DIFFERENTIAL EQUATION. Partial differential equations are extremely important in physics and engineering, and are in general difficult to solve.

If the continuity requirement for MIXED PARTIALS is dropped, it is possible to construct functions for which MIXED PARTIALS are *not* equal. An example is the function

$$f(x,\ y)=\begin{cases}\frac{xy(x^2-y^2)}{x^2+y^2} & \text{for}(x,\ y)\neq(0,\ 0)\\ 0 & \text{for}(x,\ y)=(0,\ 0),\end{cases} \tag{6}$$

which has $f_{xy}(0,\ 0)=-1$ and $f_{yx}(0,\ 0)=1$ (Wagon 1991). This function is depicted above and by Fischer (1986).

Abramowitz and Stegun (1972) give FINITE DIFFERENCE versions for partial derivatives.

Partial Differential Equation

A partial differential equation (PDE) is an equation involving functions and their PARTIAL DERIVATIVES; for example, the WAVE EQUATION

$$\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}=\frac{1}{v^2}\frac{\partial^2\psi}{\partial t^2}. \tag{1}$$

in general, partial differential equations are much more difficult to solve analytically than are ORDINARY DIFFERENTIAL EQUATIONS. They may sometimes be solved using a BÄCKLUND TRANSFORMATION, CHARACTERISTIC, GREEN'S FUNCTION, INTEGRAL TRANSFORM, LAX PAIR, SEPARATION OF VARIABLES, or–when all else fails (which it frequently does)–numerical methods.

Fortunately, partial differential equations of second-order are often amenable to analytical solution. Such PDEs are of the form

$$Au_{xx}+2Bu_{xy}+Cu_{yy}+Du_x+Eu_y+F=0. \tag{2}$$

Second-order PDEs are then classified according to the properties of the MATRIX

$$\mathsf{Z}\equiv\begin{bmatrix}A & B\\ B & C\end{bmatrix} \tag{3}$$

as ELLIPTIC, HYPERBOLIC, or PARABOLIC.

If Z is a POSITIVE DEFINITE MATRIX, i.e., $\det(\mathsf{Z})>0$, the PDE is said to be ELLIPTIC. LAPLACE'S EQUATION and POISSON'S EQUATION are examples. Boundary conditions are used to give the constraint $u(x, y)=g(x, y)$ on $\partial\Omega$, where

$$u_{xx}+u_{yy}=f(u_x, u_y, u, x, y) \tag{4}$$

holds in Ω.

If $\det(\mathsf{Z})<0$, the PDE is said to be HYPERBOLIC. The WAVE EQUATION is an example of a hyperbolic partial differential equation. Initial-boundary conditions are used to give

$$u(x, y, t)=g(x, y, t)\quad\text{for } x\in\partial\Omega,\ t>0 \tag{5}$$

$$u(x, y, 0)=v_0(x, y)\quad\text{in } \Omega \tag{6}$$

$$u_t(x, y, 0)=v_1(x, y)\quad\text{in } \Omega, \tag{7}$$

where

$$u_{xy}=f(u_x, u_t, x, y) \tag{8}$$

holds in Ω.

If $\det(\mathsf{Z})=0$, the PDE is said to be parabolic. The HEAT CONDUCTION EQUATION equation and other diffusion equations are examples. Initial-boundary conditions are used to give

$$u(x, t)=g(x, t)\quad\text{for } x\in\partial\Omega,\ t>0 \tag{9}$$

$$u(x, 0)=v(x)\quad\text{for } x\in\Omega, \tag{10}$$

where

$$u_{xx}=f(u_x, u_y, u, x, y) \tag{11}$$

holds in Ω.

Partial Fraction Decomposition

A RATIONAL FUNCTION $P(x)/Q(x)$ can be rewritten using what is known as partial fraction decomposition. This procedure often allows integration to be performed on each term separately by inspection. For each factor of $Q(x)$ the form $(ax+b)^m$, introduce terms

$$\frac{A_1}{ax+b}+\frac{A_2}{(ax+b)^2}+\ldots+\frac{A_m}{(ax+b)^m}. \quad (1)$$

For each factor OF THE FORM $(ax^2+bx+c)^m$, introduce terms

$$\frac{A_1x+B_1}{ax^2+bx+c}+\frac{A_2x+B_2}{(ax^2+bx+c)^2}+\ldots$$
$$+\frac{A_mx+B_m}{(ax^2+bx+c)^m}. \quad (2)$$

Then write

$$\frac{P(x)}{Q(x)}=\frac{A_1}{ax+b}+\ldots+\frac{A_2x+B_2}{ax^2+bx+c}+\ldots \quad (3)$$

and solve for the A_is and B_is.

Partial fraction decomposition is implemented in *Mathematica* 4.0 as Apart.

Partial Integration

INTEGRATION BY PARTS

Partial Latin Square

In a normal $n \times n$ LATIN SQUARE, the entries in each row and column are chosen from a "global" set of n objects. Like a Latin square, a partial Latin square has no two rows or columns which contain the same two symbols. However, in a partial Latin square, each cell is assigned one of its own set of n possible "local" (and distinct) symbols, chosen from an overall set of more than three distinct symbols, and these symbols may vary from location to location. For example, given the possible symbols $\{1, 2, \ldots, 6\}$ which must be arranged as

$$\begin{matrix} \{1, 2, 3\} & \{1, 3, 4\} & \{2, 5, 6\} \\ \{2, 3, 5\} & \{1, 2, 3\} & \{4, 5, 6\} \\ \{4, 3, 6\} & \{3, 5, 6\} & \{2, 3, 5\}, \end{matrix}$$

the 3×3 partial Latin square

$$\begin{matrix} 1 & 3 & 2 \\ 2 & 4 & 5 \\ 6 & 5 & 3 \end{matrix}$$

can be constructed.

See also DINITZ PROBLEM, LATIN SQUARE

Partial Order

A RELATION "$\leq$" is a partial order on a SET S if it has:

1. Reflexivity: $a \leq a$ for all $a \in S$.
2. Antisymmetry: $a \leq b$ and $b \leq a$ implies $a = b$.
3. Transitivity: $a \leq b$ and $b \leq c$ implies $a \leq c$.

For a partial order, the size of the longest CHAIN (ANTICHAIN) is called the LENGTH (WIDTH). A partially ordered set is also called a poset.

A largest set of unrelated vertices in a PARTIAL ORDER can be found using MaximumAntichain[*g*] in the *Mathematica* add-on package DiscreteMath'Combinatorica' (which can be loaded with the command <<DiscreteMath'). MinimumChainPartition[*g*] in the *Mathematica* add-on package DiscreteMath'Combinatorica' (which can be loaded with the command <<DiscreteMath') partitions a partial order into a minimum number of CHAINS.

See also ANTICHAIN, CHAIN, FENCE POSET, IDEAL (PARTIAL ORDER), LENGTH (PARTIAL ORDER), LINEAR EXTENSION, PARTIALLY ORDERED SET, TOTAL ORDER, WIDTH (PARTIAL ORDER)

Partial Quotient

If the SIMPLE CONTINUED FRACTION of a REAL NUMBER x is given by

$$x=a_0+\cfrac{1}{a_1+\cfrac{1}{a_2+\cfrac{1}{a_3+\ldots}}},$$

then the quantities a_i are called partial quotients.

See also CONTINUED FRACTION, CONVERGENT, SIMPLE CONTINUED FRACTION

Partially Ordered Set

A partially ordered set (or poset) is a SET taken together with a PARTIAL ORDER on it. Formally, a partially ordered set is defined as an ordered pair $P=(X, \leq)$, where X is called the GROUND SET of P and $\leq$ is the PARTIAL ORDER of P.

See also CIRCLE ORDER, COVER RELATION, DOMINANCE, GROUND SET, HASSE DIAGRAM, INTERVAL ORDER, ISOMORPHIC POSETS, ORDER ISOMORPHIC, PARTIAL ORDER, POSET DIMENSION, REALIZER, RELATION

Particularly Well-Behaved Functions

Functions which have DERIVATIVES of all orders at all points and which, together with their DERIVATIVES, fall off at least as rapidly as $|x|^{-n}$ as $|x| \to \infty$, no matter how large n is.

See also REGULAR SEQUENCE

Partisan Game

A GAME for which each player has a different set of moves in any position. Every position in an IMPARTIAL GAME has a NIM-VALUE.

Partition

A partition is a way of writing an INTEGER n as a sum of POSITIVE INTEGERS where the order of the summands is not significant, possibly subject to one or more additional constraints. By convention, partitions are normally written from largest to smallest summands (Skiena 1990, p. 51), e.g., $10 = 3 + 2 + 2 + 2 + 1$. `PartitionsQ[p]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``) tests a list to determine that it consists of positive integers and therefore is a valid partition. Andrews (1998, p. 1) used the notation $\lambda \vdash n$ to indicate "a sequence λ is a partition of n," and the notation $^{a_1}2^{a_2}\cdots)$ to abbreviate the partition $\{\underbrace{1,\ldots,1}_{a_1},\underbrace{2,\ldots,2}_{a_2},\ldots\}$.

Particular types of partition functions include the PARTITION FUNCTION P, giving the number of partitions of a number as a sum of smaller integers without regard to order, and PARTITION FUNCTION Q, giving the number of ways of writing the INTEGER n as a sum of POSITIVE INTEGERS without regard to order and with the constraint that all INTEGERS in each sum are distinct. The PARTITION FUNCTION b, which gives the number of partitions of n in which no parts are multiples of k is sometimes also used (Gordon and Ono 1997).

The EULER TRANSFORM b_n gives the number of partitions of n into integer parts of which there are a_1 different types of parts of size 1, a_2 of size 2, etc. For example, if $a_n = 1$ for all n, then b_n is the number of partitions of n into integer parts. Similarly, if $a_n = 1$ for n prime and $a_n = 0$ for n composite, then b_n is the number of partitions of n into prime parts (Sloane and Plouffe 1995, p. 21).

A partition of a number n into a sum of elements of a list L can be determined using a GREEDY ALGORITHM. The following table gives the number of partitions of n into a sum of positive powers p for multiples of n.

n	$p=1$	$p=2$	$p=3$	$p=4$
	Sloane's A000041	Sloane's A001156	Sloane's A003108	Sloane's A046042
10	42	4	2	1
50	204226	104	10	4
100	190569292	1116	39	9
150	40853235313	6521	97	15
200	3972999029388	27482	208	24
250	2.307×10^{14}		388	34
300	9.253×10^{15}		683	49

Partition Function b

The number of partitions of n in which no parts are multiples of k is sometimes denoted $b_k(n)$ (Gordon and Ono 1997). $b_k(n)$ is also the number of partitions of n into at most $k-1$ copies of each part.

$b_2(n) = Q(n)$, where $Q(n)$ is the PARTITION FUNCTION Q, and $b_p(n)$ is the number of irreducible p-modular representations of the SYMMETRIC GROUP S_n. The generating function for $b_k(n)$ is given by

$$\sum_{n=0}^{\infty} b_k(n) x^n = \prod_{n=1}^{\infty} \frac{1 - x^{kn}}{1 - x^n}. \qquad (1)$$

The following table gives the first few values of $b_k(n)$ for small k.

k	Sloane	$b_k(n)$
2	A000009	1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18, 22, ...
3	A000726	1, 2, 2, 4, 5, 7, 9, 13, 16, 22, 27, 36, 44, 57, ...
4	A001935	1, 2, 3, 4, 6, 9, 12, 16, 22, 29, 38, 50, 64, 82, ...
5	A035959	1, 2, 3, 5, 6, 10, 13, 19, 25, 34, 44, 60, 76, 100, ...

Gordon and Ono (1997) show that

$$b_5(5n+4) \equiv 0 \pmod{5} \qquad (2)$$

$$b_7(7n+5) \equiv 0 \pmod{7} \qquad (3)$$

$$b_{11}(11n+6) \equiv 0 \pmod{11}. \qquad (4)$$

Defining $S_k(N;\ M)$ as the number of positive integers $n \leq N$ for which $b_k(n) \equiv 0 \pmod{M}$, Gordon and Ono (1997) proved that if $p_i^{a_i} \geq \sqrt{k}$, then

$$\lim_{N \to \infty} \frac{S_k(N;\ p_i^j)}{N} = 1 \qquad (5)$$

for all j, where $k = p_1^{a_1} p_2^{a_2} \cdots p_m^{a_m}$.

Partition Function P

$P(n)$, denotes also denoted $p(n)$, gives the number of ways of writing the INTEGER n as a sum of POSITIVE INTEGERS, where the order of summands is not considered significant. By convention, partitions are usually ordered from largest to smallest (Skiena 1990, p. 51). For example, since 4 can be written

$$\begin{aligned} 4 &= 4 \\ &= 3+1 \\ &= 2+2 \\ &= 2+1+1 \\ &= 1+1+1+1 \end{aligned} \qquad (1)$$

it follows that $P(4) = 5$. The function $P(n)$ is implemented in *Mathematica* as `PartitionsP[n]`. The values of $P(n)$ for $n = 1, 2, ...,$ are 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, ... (Sloane's A000041). The following table gives the value of $P(n)$ for selected small n.

n	$P(n)$
50	204226
100	190569292
200	3972999029388
300	9253082936723602
400	6727090051741041926
500	2300165032574323995027
600	458004788008144308553622
700	60378285202834474611028659
800	5733052172321422504456911979
900	415873681190459054784114365430
1000	24061467864032622473692149727991

When explicitly listing the partitions of a number n, the simplest form is the so-called *natural representation* which simply gives the sequence of numbers in the representation (e.g., (2, 1, 1) for the number $4 = 2+1+1$). The *multiplicity representation* instead gives the number of times each number occurs together with that number (e.g., (2, 1), (1, 2) for $4 = 2 \cdot 1 + 1 \cdot 2$). The FERRERS DIAGRAM is a pictorial representation of a partition. For example, the dia-

gram above illustrates the FERRERS DIAGRAM of the partition $6+3+3+2+1=15$.

Euler gave a GENERATING FUNCTION for $P(n)$ using the Q-SERIES

$$(q)_\infty \equiv \prod_{m=1}^{\infty}(1-q^m) = \sum_{n=-\infty}^{\infty}(-1)^n q^{(3n+1)/2} \quad (2)$$

$$= 1-q-q^2+q^5+q^7-q^{12}-q^{15}+q^{22}+q^{26}+\ldots. \quad (3)$$

Here, the exponents are generalized PENTAGONAL NUMBERS 0, 1, 2, 5, 7, 12, 15, 22, 26, 35, ... (Sloane's A001318) and the sign of the kth term (counting 0 as the 0th term) is $(-1)^{\lfloor (k+1)/2 \rfloor}$ (with $\lfloor x \rfloor$ the FLOOR FUNCTION). Then the partition numbers $P(n)$ are given by the GENERATING FUNCTION

$$\frac{1}{(q)_\infty} = \sum_{n=0}^{\infty} P(n)q^n = 1+q+2q^2+3q^3+5q^4+\ldots \quad (4)$$

(Hirschhorn 1999). Hirschhorn (1999) gives the additional beautiful identity

$$\frac{1}{(q)_\infty} = \frac{(q)_\infty^9}{(q)_\infty^{10}} = \frac{((q)_\infty^3)^3}{((q)_\infty^5)^2}. \quad (5)$$

Another GENERATING FUNCTION is given by

$$\sum_{n=0}^{\infty} P(n)t^n = \left(\frac{2t^{1/8}}{\vartheta_1'(0, \sqrt{t})}\right)^{1/3}, \quad (6)$$

where $\vartheta_1'(0, x)$ is the derivative of the JACOBI THETA FUNCTION of the first kind.

The number of partitions of a number n into m parts is equal to the number of partitions into parts of which the largest is m, and the number of partitions into at most m parts is equal to the number of partitions into parts which do not exceed m. Both these results follow immediately from noting that a FERRERS DIAGRAM can be read either row-wise or column-wise (although the default order is row-wise; Hardy 1999, p. 83).

For example, if $a_n = 1$ for all n, then the EULER TRANSFORM b_n is the number of partitions of n into integer parts.

Euler invented a GENERATING FUNCTION which gives rise to a POWER SERIES in $P(n)$,

$$P(n) = \sum_{k=1}^{n}(-1)^{k+1} \times \left[P\left(n-\tfrac{1}{2}k(3k-1)\right) + P\left(n-\tfrac{1}{2}k(3k+1)\right)\right] \quad (7)$$

(Skiena 1990, p. 57). Other recurrence formulas include

$$P(2n+1) = P(n) + \sum_{k=1}^{\infty}\left[P\left(n-4k^2-3k\right)+P\left(n-4k^2+3k\right)\right] - \sum_{k=1}^{\infty}(-1)^k\left[P\left(2n+1-3k^2+k\right) + P\left(2n+1-3k^2-k\right)\right] \quad (8)$$

and

$$P(n) = \frac{1}{n}\sum_{k=0}^{n-1}\sigma(n-k)P(k), \quad (9)$$

where $\sigma(n)$ is the DIVISOR FUNCTION (Skiena 1990, p. 77; Berndt 1994, p. 108), as well as the identity

$$\sum_{k=\lceil -(\sqrt{24n+1}+1)/6 \rceil}^{\lfloor (\sqrt{24n+1}-1)/6 \rfloor}(-1)^k P\left(n-\tfrac{1}{2}k(3k+1)\right) = 0, \quad (10)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\lceil x \rceil$ is the CEILING FUNCTION.

A RECURRENCE RELATION involving the PARTITION FUNCTION Q is given by

$$P(n) = \sum_{k=0}^{\lfloor n/2 \rfloor} Q(n-2k)P(k). \quad (11)$$

Atkin and Swinnerton-Dyer (1954) obtained the unexpected identities

$$\sum_{n=0}^{\infty} P(5n)q^n \equiv \prod_{n=1}^{\infty}\frac{(1-q^{5n-3})(1-q^{5n-2})(1-q^{5n})}{(1-q^{5n-4})^2(1-q^{5n-1})^2} \pmod 5 \quad (12)$$

$$\sum_{n=0}^{\infty} P(5n+1)q^n \equiv \prod_{n=1}^{\infty}\frac{(1-q^{5n})}{(1-q^{5n-4})(1-q^{5n-1})} \pmod 5 \quad (13)$$

$$\sum_{n=0}^{\infty} P(5n+2)q^n \equiv 2\prod_{n=1}^{\infty}\frac{(1-q^{5n})}{(1-q^{5n-3})(1-q^{5n-2})} \pmod 5 \quad (14)$$

$$\sum_{n=0}^{\infty} P(5n+3)q^n \equiv 3\prod_{n=1}^{\infty}\frac{(1-q^{5n-4})(1-q^{5n-1})(1-q^{5n})}{(1-q^{5n-3})^2(1-q^{5n-2})^2} \pmod 5 \quad (15)$$

(Hirschhorn 1999).

MacMahon obtained the beautiful RECURRENCE RELATION

$$P(n)-P(n-1)-P(n-2)+P(n-5)+P(n-7)$$
$$-P(n-12)-P(n-15)+\ldots=0, \tag{16}$$

where the sum is over generalized PENTAGONAL NUMBERS $\leq n$ and the sign of the kth term is $(-1)^{\lfloor (k+1)/2 \rfloor}$, as above. Ramanujan stated without proof the remarkable identities

$$P(4)+P(9)x+P(14)x^2+\ldots$$
$$=5\,\frac{[(1-x^5)(1-x^{10})(1-x^{15})\cdots]^5}{[(1-x)(1-x^2)(1-x^3)\cdots]^6} \tag{17}$$

(Darling 1921; Mordell 1922; Hardy 1999, pp. 89–90), and

$$P(5)+P(12)x+P(17)x^2+\ldots$$
$$=7\,\frac{[(1-x^7)(1-x^{14})(1-x^{21})\cdots]^3}{[(1-x)(1-x^2)(1-x^3)\cdots]^4}$$
$$+49x\,\frac{[(1-x^7)(1-x^{14})(1-x^{21})\cdots]^7}{[(1-x)(1-x^2)(1-x^3)\cdots]^8} \tag{18}$$

(Mordell 1922; Hardy 1999, pp. 89–90).

Hardy and Ramanujan (1918) used the CIRCLE METHOD and MODULAR FUNCTIONS to obtain the asymptotic solution

$$P(n)\sim\frac{1}{4n\sqrt{3}}\,e^{\pi\sqrt{2n/3}} \tag{19}$$

(Hardy 1999, p. 116), which was also independently discovered by Uspensky (1920). Rademacher (1937) subsequently obtained an exact convergent series solution which yields the Hardy-Ramanujan formula (19) as the first term:

$$P(n)=\frac{1}{\pi\sqrt{2}}\sum_{k=1}^{\infty}A_k(n)\sqrt{k}$$
$$\times\left\{\frac{d}{dn'}\left[\frac{\sinh\left(\frac{\pi}{k}\sqrt{\frac{2}{3}\left(n'-\frac{1}{24}\right)}\right)}{\sqrt{n'-\frac{1}{24}}}\right]\right\}_{n'=n}, \tag{20}$$

where

$$A_k(n)=\sum_{h=1}^{k}\delta_{\mathrm{GCD}(h,\,k),\,1}$$
$$\times\exp\left[\pi i\sum_{j=1}^{k-1}\frac{i}{k}\left(\frac{hj}{k}-\left\lfloor\frac{hj}{k}\right\rfloor-\frac{1}{2}\right)-\frac{2\pi ihn}{k}\right], \tag{21}$$

δ_{mn} is the KRONECKER DELTA, and $\lfloor x \rfloor$ is the FLOOR FUNCTION (Hardy 1999, pp. 120–121). The remainder after N terms is

$$R(N)<CN^{-1/2}+D\sqrt{\frac{N}{n}}\sinh\left(\frac{K\sqrt{n}}{N}\right), \tag{22}$$

where C and D are fixed constants (Apostol 1997, pp. 104–110; Hardy 1999, pp. 121 and 128). Rather amazingly, the CONTOUR used by Rademacher involves FAREY SEQUENCES and FORD CIRCLES (Apostol 1997, pp. 102–104; Hardy 1999, pp. 121–122). In 1942, Erdos showed that the formula of Hardy and Ramanujan could be derived by elementary means (Hoffman 1998, p. 91).

With $f(x)$ as defined above, Ramanujan also showed that

$$5\,\frac{(q^5)_\infty^5(x^5)}{(q)_\infty^6}=\sum_{m=0}^{\infty}P(5m+4)x^m. \tag{23}$$

Ramanujan also found numerous PARTITION FUNCTION P CONGRUENCES.

Let $f_O(x)$ be the GENERATING FUNCTION for the number of partitions $P_O(n)$ of n containing ODD numbers only and $f_D(x)$ be the GENERATING FUNCTION for the number of partitions $P_D(n)$ of n without duplication, then

$$f_O(x)=f_D(x)=\prod_{k=1,\,3,\,\ldots}^{\infty}\sum_{i=0}^{\infty}x^{ik}$$
$$=\frac{1}{\prod_{k=1,\,3,\,\ldots}^{\infty}1-x^k}$$
$$=\prod_{k=1}^{\infty}(1+x^k)=1+x+x^2$$
$$+2x^3+2x^4+3x^5+\ldots, \tag{24}$$

as discovered by Euler (Honsberger 1985; Andrews 1998, p. 5; Hardy 1999, p. 86), giving the first few values of $P_O(n)=P_D(n)$ for $n=0, 1, \ldots$ as 1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, ... (Sloane's A000009). The identity

$$\prod_{k=1}^{\infty}(1+z^k)=\prod_{k=1}^{\infty}(1+z^{2k-1})^{-1}, \tag{25}$$

$$=1-x-x^2+x^5+x^7-x^{12}-x^{15}+\ldots \tag{26}$$

$$=1+\sum_{k=1}^{\infty}c_k, \tag{27}$$

where

$$c_k=\begin{cases}(-1)^n & \text{for } k \text{ of the form } \frac{1}{2}n(3n\pm 1)\\ 0 & \text{otherwise,}\end{cases} \tag{28}$$

which is the GENERATING FUNCTION for the difference between the number of partitions into an even number of unequal parts and the number of partitions in an odd number of unequal parts, is known as the EULER IDENTITY (Hardy 1999, p. 84).

Let $P_E(n)$ be the number of partitions of EVEN numbers only, and let $P_{EO}(n)$ ($P_{DO}(n)$) be the number of partitions in which the parts are all EVEN (ODD) and all different. Then the GENERATING FUNCTION of $P_{DO}(n)$ is given by

$$f_{DO}(n) = \prod_{k=1,\ 3,\ \ldots}^{\infty} 1 + x^k \tag{29}$$

(Hardy 1999, p. 86), and the first few values of are 1, 1, 0, 1, 1, 1, 1, 1, 2, 2, 2, 2, 3, 3, 3, 4, ... (Sloane's A000700). Some additional GENERATING FUNCTIONS are given by Honsberger (1985, pp. 241–242)

$$\sum_{n=1}^{\infty} P_{\text{no even part repeated}}(n)x^n$$

$$= \prod_{k=1} (1-x^{2k-1})^{-1}(1+x^{2k}) \tag{30}$$

$$\sum_{n=1}^{\infty} P_{\text{no part occurs more than 3 times}}(n)x^n$$

$$= \prod_{k=1} (1+x^k+x^{2k}+x^{3k}) \tag{31}$$

$$\sum_{n=1}^{\infty} P_{\text{no part divisible by 4}}(n)x^n = \prod_{k=1} \frac{1-x^{4k}}{1-x^k} \tag{32}$$

$$\sum_{n=1}^{\infty} P_{\text{no part occurs more than } d \text{ times}}(n)x^n$$

$$= \prod_{k=1} \sum_{i=0}^{d} x^{ik} = \prod_{k=1} \frac{1-x^{(d+1)k}}{1-x^k} \tag{33}$$

$$\sum_{n=1}^{\infty} P_{\text{every part occurs 2, 3, or 5 times}}(n)x^n$$

$$= \prod_{k=1} (1+x^{2k}+x^{3k}+x^{5k})$$

$$= \prod_{k=1} (1+x^{2k})(1+x^{3k}) = \prod_{k=1} \frac{1-x^{4k}}{1-x^{2k}}\frac{1-x^{6k}}{1-x^{3k}} \tag{34}$$

$$\sum_{n=1}^{\infty} P_{\text{no part occurs exactly once}}(n)x^n$$

$$= (1+x^{2k}+x^{3k}+\ldots) = \prod_{k} \frac{1+x^{6k}}{(1-x^{2k})(1-x^{3k})}. \tag{35}$$

Some additional interesting theorems following from these (Honsberger 1985, pp. 64–68 and 143–146) are:

1. The number of partitions of n in which no EVEN part is repeated is the same as the number of partitions of n in which no part occurs more than three times and also the same as the number of partitions in which no part is divisible by four.
2. The number of partitions of n in which no part occurs more often than d times is the same as the number of partitions in which no term is a multiple of $d+1$.
3. The number of partitions of n in which each part appears either 2, 3, or 5 times is the same as the number of partitions in which each part is CONGRUENT mod 12 to either 2, 3, 6, 9, or 10.
4. The number of partitions of n in which no part appears exactly once is the same as the number of partitions of n in which no part is CONGRUENT to 1 or 5 mod 6.
5. The number of partitions in which the parts are all EVEN and different is equal to the absolute difference of the number of partitions with ODD and EVEN parts.

$P(n)$ satisfies the inequality

$$P(n) \le \tfrac{1}{2}[(n+1)+P(n-1)] \tag{36}$$

(Honsberger 1991).

$P(n, k)$, also written $P_k(n)$, is the number of ways of writing n as a sum of k terms or, equivalently, the number of partitions into parts of which the largest is k. The latter can be enumerated by `Partitions[n, k]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``). For example, the $P(5, 3)=5$ partitions of 5 of which the largest member is ≤ 3 are {3, 2}, {3, 1, 1}, {2, 2, 1}, {2, 1, 1, 1}, and {1, 1, 1, 1, 1}. Similarly, the five partitions of 5 into three or fewer parts are {5}, {4, 1}, {3, 2}, {3, 1, 1}, and {2, 2, 1}.

$P(n, k)$ is implemented as `ConstrainedIntegerPartitionsP[n, k]` in the *Mathematica* add-on package `DiscreteMath`IntegerPartitions`` (which can be loaded with the command `<<DiscreteMath``), and can be computed from the RECURRENCE RELATION

$$P(n, k) = P(n-1, k-1) + P(n-k, k) \tag{37}$$

(Skiena 1990, p. 58; Ruskey) with $P(n, k)=0$ for $k>n$, $P(n, n)=1$, and $P(n, 0)=0$. The triangle of $P(k, n)$ is given by

1

1 1

1 1 1

1 2 1 1

1 2 2 1 1

1 3 3 2 1 1

(Sloane's A008284). The number of partitions of n with largest part k is the same as $P(n, k)$.

The RECURRENCE RELATION can be solved exactly to give

$$P(n,\ 1)=1 \quad (38)$$

$$P(n,\ 2)=\tfrac{1}{4}\left[2n-1+(-1)^n\right] \quad (39)$$

$$P(n,\ 3)=\tfrac{1}{72}\left[6n^2-7-9(-1)^n+16\cos\left(\tfrac{2}{3}n\pi\right)\right] \quad (40)$$

$$P(n,\ 4)=\tfrac{1}{864}\{3(n+1)[2n(n+2)-13+9(-1)^n] -96\cos\left(\tfrac{2}{3}n\pi\right)+108(-1)^{n/2}\operatorname{mod}(n+1,\ 2) +32\sqrt{3}\sin(\tfrac{2}{3}n\pi)\}, \quad (41)$$

where $P(n,\ k)=0$ for $n<k$. The functions $P(n,\ k)$ can also be given explicitly for the first few values of k in the simple forms

$$P(n,\ 2)=\left\lfloor\tfrac{1}{2}n\right\rfloor \quad (42)$$

$$P(n,\ 3)=\left[\tfrac{1}{12}n^2\right], \quad (43)$$

where $\lfloor x\rfloor$ is the FLOOR FUNCTION and $[x]$ is the NINT function (Honsberger 1985, pp. 40–45). A similar treatment by B. Schwennicke defines

$$t_k(n)=n+\tfrac{1}{4}k(k-3) \quad (44)$$

and then yields

$$P(n,\ 2)=\left[\tfrac{1}{2}t_2(n)\right] \quad (45)$$

$$P(n,\ 3)=\left[\tfrac{1}{12}t_2^3(n)\right] \quad (46)$$

$$P(n,\ 4)=\begin{cases}\left[\tfrac{1}{144}t_4^3(n)-\tfrac{1}{48}t_4(n)\right] & \text{for } n \text{ even}\\ \left[\tfrac{1}{144}t_4^3(n)-\tfrac{1}{12}t_4(n)\right] & \text{for } n \text{ odd.}\end{cases} \quad (47)$$

Hardy and Ramanujan (1918) obtained the exact asymptotic formula

$$P(n)=\sum_{k<\alpha\sqrt{n}} P_k(n)+\mathcal{O}(n^{-1/4}), \quad (48)$$

where α is a constant. However, the sum

$$\sum_{k=1}^{\infty} P_k(n) \quad (49)$$

diverges, as first shown by Lehmer (1937).

Partition Function P Congruences

The fraction of odd values of the PARTITION FUNCTION P is roughly 50%, independent of n, whereas odd values of $Q(n)$ occur with ever decreasing frequency as n becomes large. Kolberg (1959) proved that there are infinitely many even and odd values of $P(n)$.

Leibniz noted that $P(n)$ is prime for $n = 2, 3, 4, 5, 6$, but not 7. In fact, values of n for which $P(n)$ is PRIME are 2, 3, 4, 5, 6, 13, 36, 77, 132, 157, 168, 186, ... (Sloane's A046063), corresponding to 2, 3, 5, 7, 11, 101, 17977, 10619863, ... (Sloane's A049575). Numbers which cannot be written as a PRODUCT of $P(n)$ are 13, 17, 19, 23, 26, 29, 31, 34, 37, 38, 39, ... (Sloane's A046064), corresponding to numbers of nonisomorphic ABELIAN GROUPS which are not possible for any group order.

Ramanujan conjectured a number of amazing and unexpected CONGRUENCES involving $P(n)$. In particular, he proved

$$P(5m+4) \equiv 0 \pmod{5} \tag{1}$$

using RAMANUJAN'S IDENTITY (Darling 1919; Hardy and Wright 1979; Drost 1997; Hardy 1999, pp. 87–88; Hirschhorn 1999). Ramanujan (1919) also showed that

$$P(25m+24) \equiv 0 \pmod{5^2}, \tag{2}$$

and Krecmar (1933) proved that

$$P(125m+99) \equiv 0 \pmod{5^3}. \tag{3}$$

Watson (1938) then proved the general congruence

$$P(n) \equiv 0 \pmod{5^a} \quad \text{if } 24n \equiv 1 \pmod{5^a} \tag{4}$$

(Gordon and Hughes 1981; Hardy 1999, p. 89). For $a = 1, 2, ...$, the corresponding minimal values of n are 4, 24, 99, 599, 2474, 14974, 61849, ... (Sloane's A052463). However, the even more general congruences

$$P(125m+74,\ 99,\ 124) \equiv 0 \pmod{5^3} \tag{5}$$

$$P(3125m+1849,\ 2474,\ 3099) \equiv 0 \pmod{5^5} \tag{6}$$

seem also to hold.

Ramanujan showed that

$$P(7m+5) \equiv 0 \pmod{7} \tag{7}$$

(Darling 1919), which can be derived using the EULER IDENTITY and JACOBI TRIPLE PRODUCT (Hardy 1999, pp. 87–88), and also that

$$P(49m+47) \equiv 0 \pmod{7^2} \tag{8}$$

(Hardy 1999, p. 90). He conjectured that in general

$$P(n) \equiv 0 \pmod{7^b} \quad \text{if } 24n \equiv 1 \pmod{7^b} \quad \text{[incorrect]} \tag{9}$$

(Gordon and Hughes 1981, Hardy 1999), although Gupta (1936) showed that this is *false* when $b = 3$. Watson (1938) subsequently formulated and proved the modified relation

$$P(n) \equiv 0 \pmod{7^b} \quad \text{if } 24n \equiv 1 \pmod{7^{2b-2}} \tag{10}$$

for $b \geq 2$. For $b = 1, 2, ...$, the corresponding minimal values of n are 0, 47, 2301, 112747, ... (Sloane's A052464). However, the even more general congruences

$$P(49m+19,\ 33,\ 40,\ 47) \equiv 0 \pmod{7^2} \tag{11}$$

appear to hold.

Ramanujan showed that

$$P(11m+6) \equiv 0 \pmod{11} \tag{12}$$

holds (Gordon and Hughes 1981; Hardy 1999, pp. 87–88), and conjectured the general relation

$$P(n) \equiv 0 \pmod{11^c} \quad \text{if } 24n \equiv 1 \pmod{11^c}. \tag{13}$$

This was finally proved by Atkin (1967). For $c = 1, 2, ...$, the corresponding minimal values of n are 6, 116, 721, 14031, ... (Sloane's A052465).

Atkin and O'Brien (1967) proved

$$P(169n-7) \equiv \kappa_d P(n) \pmod{13^d} \quad \text{if } 24n \equiv 1 \pmod{13^d}, \tag{14}$$

where κ_d is an integer depending only on d (Gordon and Hughes 1981). For $d = 1, 2, ...$, the corresponding minimal values of n are 6, 162, 1007, 27371, ... (Sloane's A052466).

Subbarao (1966) conjectured that in every ARITHMETIC PROGRESSION $r \pmod t$, there are infinitely many integers $N \equiv r \pmod t$ for which $P(N)$ is EVEN, and infinitely many integer $M \equiv r \pmod t$ for which $P(M)$ is ODD.

Partition Function q

The number of PARTITIONS of n with $\leq k$ summands is denoted $q(n, k)$ or $q_k(n)$. For example, $q(10, 2) = 6$, since there are six partitions of 10 into two or fewer parts: {10}, {9, 1}, {8, 2}, {7, 3}, {6, 4}, and {5, 5}. The $q(n, k)$ satisfy the RECURRENCE RELATION

$$q(n, k) = q(n, k-1) + q(n-k, k), \tag{1}$$

with $q(n, 0) = 0$, $q(1, k) = 1$, and $q(n, k) = P(n)$ for $k \geq n$. The triangle of $q(n, k)$ is given by

1

1 2

1 2 3

1 3 4 5

1 3 5 6 7

1 4 7 9 10 11

(Sloane's A026820).

Partition Function Q

$Q(n)$ gives the number of ways of writing the INTEGER n as a sum of POSITIVE INTEGERS without regard to order with the constraint that all INTEGERS in a given partition are *distinct*. For example, $Q(10) = 10$, since the partitions of 10 into distinct parts are {1, 2, 3, 4}, {2, 3, 5}, {1, 4, 5}, {1, 3, 6}, {4, 6}, {1, 2, 7}, {3, 7}, {2, 8}, {1, 9}, {10}. The $Q(n)$ function is implemented in *Mathematica* as `PartitionsQ[n]`. $Q(0)$ is generally defined to be 1. The values for $n = 1, 2, ...$ are 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, ... (Sloane's A000009).

The GENERATING FUNCTION for $Q(n)$ is

$$G(x) = \prod_{n=1}^{\infty}(1+x^n) \quad (1)$$

$$= \frac{1}{\prod_{n=0}^{\infty}(1-x^{2n+1})} \quad (2)$$

$$= \prod_{n=1}^{\infty}\frac{1-x^{2n}}{1-x^n} \quad (3)$$

$$= 1+x+x^2+2x^3+2x^4+3x^5+\ldots. \quad (4)$$

This can also be interpreted as another form of the JACOBI TRIPLE PRODUCT, written in terms of the Q-FUNCTIONS as

$$Q_1Q_2Q_3 = 1 \quad (5)$$

(Borwein and Borwein 1987, p. 64).

A RECURRENCE RELATION is given by $Q(0)=Q(1)=1$ and

$$Q(n) = \frac{1}{n}\sum_{k=1}^{n}[s(k)-2s(k/2)]Q(n-k), \quad (6)$$

where

$$s(n) = \begin{cases} \sigma_1(n) & \text{for } n \text{ an integer} \\ 0 & \text{otherwise,} \end{cases} \quad (7)$$

and

$$\sigma_1(n) \equiv s(n) - 2s(n/2) \quad (8)$$

is the ODD DIVISOR FUNCTION giving the sum of odd divisors of n: 1, 1, 4, 1, 6, 4, 8, ... (Sloane's A000593; Abramowitz and Stegun 1972, p. 826).

$Q(n)$ satisfies the inequality

$$Q(n) \leq \tfrac{1}{2}[Q(n+1)+Q(n-1)] \quad (9)$$

for $n \geq 4$. $Q(n)$ has the ASYMPTOTIC SERIES

$$Q(n) \sim \frac{e^{\pi\sqrt{n/3}}}{4\cdot 3^{1/4}n^{3/4}} \quad (10)$$

(Abramowitz and Stegun 1972, p. 826).

A Rademacher-like convergent series for $Q(n)$ is given by

$$Q(n) = \tfrac{1}{2}\sqrt{2}\sum_{k=1}^{\infty}A_{2k-1}(n) \times \left\{\frac{d}{dn'}\left[J_0\left(\frac{\pi i}{2k-1}, \sqrt{\tfrac{1}{3}\left(n'+\tfrac{1}{24}\right)}\right)\right]\right\}_{n'=n}, \quad (11)$$

where

$$A_k(n) = \sum_{h=1}^{k}\delta_{\mathrm{GCD}(h,k),1} \times \exp\left[\pi i \sum_{j=1}^{k-1}\frac{i}{k}\left(\frac{hj}{k}-\left\lfloor\frac{hj}{k}\right\rfloor-\frac{1}{2}\right)-\frac{2\pi i h n}{k}\right], \quad (12)$$

where δ_{mn} is the KRONECKER DELTA, $\lfloor x \rfloor$ is the FLOOR FUNCTION, and $J_0(x)$ is the zeroth order BESSEL FUNCTION OF THE FIRST KIND (Abramowitz and Stegun 1972, p. 825). (11) can also be written explicitly as

$$Q(n) = \frac{\pi^2\sqrt{2}}{24}\sum_{k=1}^{\infty}\frac{A_{2k-1}(n)}{(1-2k)^2}\,{}_0F_1\left(;\ 2;\ \frac{(1+24n)\pi^2}{288(1-2k)^2}\right), \quad (13)$$

where ${}_0F_1(;\ a;\ b;\ z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION.

Let $Q(n,\ k)$ denote the number of ways of partitioning n into exactly k *distinct* parts. For example, $Q(10,\ 3)=4$ since there are four partitions of 10 into three distinct parts: {1, 2, 7}, {1, 3, 6}, {1, 4, 5}, and {2, 3, 5}. $Q(n,\ k)$ is given by

$$Q(n,\ k) = P\left(n-\binom{k}{2},\ k\right), \quad (14)$$

where $P(n)$ is the PARTITION FUNCTION P and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Comtet 1974, p. 116). The following table gives the first few values of $Q(n,\ k)$ (Sloane's A008289; Comtet 1974, pp. 115–116).

$n \backslash k$	1	2	3	4
1	1			
2	1			
3	1	1		
4	1	1		
5	1	2		
6	1	2	1	
7	1	3	1	
8	1	3	2	
9	1	4	3	
10	1	4	4	1

Partition Function Q Congruences

Odd values of $Q(n)$ are 1, 1, 3, 5, 27, 89, 165, 585, ... (Sloane's A051044), and occur with ever decreasing frequency as n becomes large (unlike $P(n)$, for which the fraction of odd values remains roughly 50%). This follows from the PENTAGONAL NUMBER THEOREM which gives

$$G(x) = \prod_{n=1}^{\infty}(1+x^n) \equiv \prod_{n=1}^{\infty}(1-x^n)$$
$$\equiv \sum_{n=-\infty}^{\infty} x^{(3n^2+n)/2} \pmod 2 \qquad (1)$$

(Gordon and Ono 1997), so $Q(n)$ is ODD IFF n is OF THE FORM $k(3k \pm 1)/2$, i.e., 1, 5, 12, 22, 35, ... or 2, 7, 15, 26, 40, ...

The values of n for which $Q(n)$ is PRIME are 3, 4, 5, 7, 22, 70, 100, 495, 1247, 2072, 320397, ... (Sloane's A035359), with no others for $n \leq 3,015,000$ (Weisstein, May 6, 2000). These values correspond to 2, 2, 3, 5, 89, 29927, 444793, 602644050950309, ... (Sloane's A051005). It is not known if $Q(n)$ is infinitely often prime, but Gordon and Ono (1997) proved that it is "almost always" divisible by any given power of 2 (1997).

Gordon and Hughes (1981) showed that

$$Q(n) \equiv 0 \pmod{5^a} \quad \text{if } 24n \equiv -1 \pmod{5^{2a+1}} \qquad (2)$$

and

$$Q(n) \equiv 49n + 2 \pmod{\lambda_b Q(n)} 7^b \quad \text{if } 24n \equiv -1 \pmod{7^b}, \qquad (3)$$

where λ_b is an integer depending only on b.

Partition of Unity

Given a SMOOTH MANIFOLD M with an OPEN COVER U_i, a partition of unity is a collection of smooth, nonnegative functions ψ_i, such that the support of ψ_i is contained in U_i and $\Sigma_i\ \psi_i = 1$ everywhere. Often one requires that the U_i have COMPACT CLOSURE, which can be interpreted as finite, or bounded, open sets. In the case that the U_i is a LOCALLY finite cover, any point $x \in M$ has only finitely many i with $\psi_i(x) \neq 0$.

A partition of unity can be used to patch together objects defined locally. For instance, there always exist smooth GLOBAL VECTOR FIELDS, possibly vanishing somewhere, but not identically zero. Cover M with coordinate charts U_i such that only finitely many overlap at any point. On each coordinate chart U_i, there are the local vector fields $\partial/\partial x_j$. Label these $v_{i,j}$ and, for each chart, pick the vector field $v_{i,1} = \partial/\partial x_1$. Then $\Sigma_i\ \psi_i v_{i,1}$ is a global vector field. The sum converges because at any x, only finitely many $\psi_i(x) \neq 0$.

Other applications require the objects to be interpreted as functions, or a generalization of functions called SECTIONS, such as a RIEMANNIAN METRIC. By viewing such a metric as a section of a bundle, it is easy to show the existence of a smooth metric on any smooth manifold. The proof uses a partition of unity and is similar to the one used above.

Strictly speaking, the sum $\Sigma_i\ \psi_i$ doesn't have to be identically UNITY for the arguments to work. It goes with the name, because at every point the functions partition the value 1. Also, it is convenient when considered from the point of view of CONVEXITY.

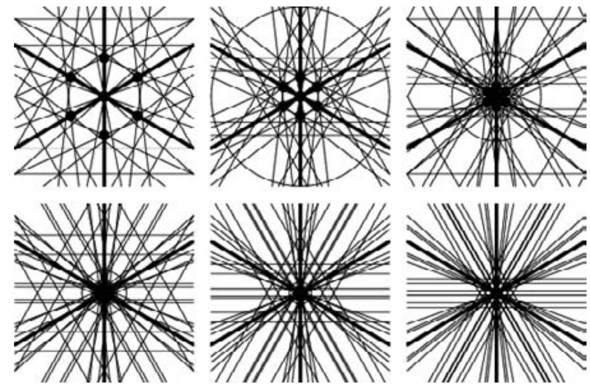
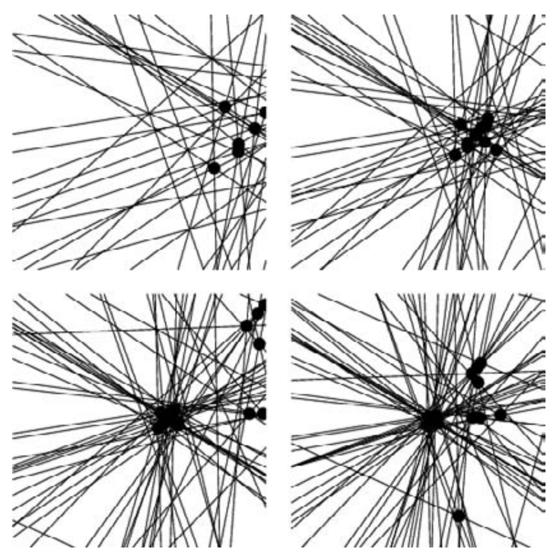
Pascal Distribution

NEGATIVE BINOMIAL DISTRIBUTION

Pascal Lines



The lines containing the three points of the intersection of the three pairs of opposite sides of a (not necessarily regular) HEXAGON.



There are 6! (i.e., 6 FACTORIAL) possible ways of taking all VERTICES in any order, but among these are six equivalent CYCLIC PERMUTATIONS and two possible orderings, so the total number of different hexagons (not all simple) is

$$\frac{6!}{2\cdot 6}=\frac{720}{12}=60.$$

There are therefore a total of 60 Pascal lines created by connecting VERTICES in any order.

The 60 Pascal lines form a very complicated pattern which can be visualized most easily in the degenerate case of a regular hexagon inscribed in a circle, as illustrated above for magnifications ranging over five powers of 2. Only 45 lines are visible in this figure since each of the three thick lines (located at 60° angles to each other) represents a degenerate group of four Pascal lines, and six of the Pascal lines are LINES AT INFINITY (Wells 1991).

The pattern for a general ellipse and hexagon (illustrated above) is much more complicated, and is difficult to distinguish from a clutter of lines.

The 60 Pascal lines intersect three at a time through 20 STEINER POINTS (some of which are shown as the filled circles in the above figures). In the symmetrical case of the regular hexagon inscribed in a CIRCLE, the 20 Steiner points degenerate into seven distinct points arranged at the vertices and center of a regular

hexagon centered at the origin of the circle. The 60 Pascal line also intersect three at a time in 60 KIRKMAN POINTS. Each Steiner point lines together with three Kirkman points on a total of 20 CAYLEY LINES. There is a dual relationship between the 60 Pascal lines and the 60 KIRKMAN POINTS.

Pascal's Formula

Each subsequent row of PASCAL'S TRIANGLE is obtained by adding the two entries diagonally above. This follows immediately from the BINOMIAL COEFFICIENT identity

$$\begin{aligned}\binom{n}{r} &\equiv \frac{n!}{(n-r)!r!} = \frac{(n-1)!n}{(n-r)!r!} \\ &= \frac{(n-1)!(n-r)}{(n-r)!r!} + \frac{(n-1)!r}{(n-r)!r!} \\ &= \frac{(n-1)!}{(n-r-1)!r!} + \frac{(n-1)!}{(n-r)!(r-1)!} \\ &= \binom{n-1}{r} + \binom{n-1}{r-1}.\end{aligned}$$

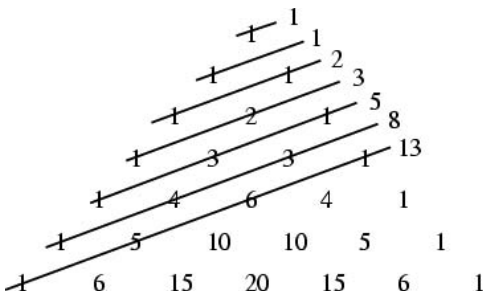
Pascal's Triangle

A TRIANGLE of numbers arranged in staggered rows such that



$$a_{nr} \equiv \frac{n!}{r!(n-r)!} \equiv \binom{n}{r}, \tag{1}$$

where $\binom{n}{r}$ is a BINOMIAL COEFFICIENT. The triangle was studied by B. Pascal, although it had been described centuries earlier by Chinese mathematician Yanghui (about 500 years earlier, in fact) and the Persian astronomer-poet Omar Khayyám. It is therefore known as the Yanghui triangle in China. Starting with $n = 0$, the TRIANGLE is

$$\begin{array}{c} 1 \\ 1\quad 1 \\ 1\quad 2\quad 1 \\ 1\quad 3\quad 3\quad 1 \\ 1\quad 4\quad 6\quad 4\quad 1 \\ 1\quad 5\quad 10\quad 10\quad 5\quad 1 \\ 1\quad 6\quad 15\quad 20\quad 15\quad 6\quad 1 \end{array}$$

(Sloane's A007318). PASCAL'S FORMULA shows that each subsequent row is obtained by adding the two entries diagonally above,

$$\binom{n}{r} = \frac{n!}{(n-r)!r!} = \binom{n-1}{r} + \binom{n-1}{r-1}. \tag{2}$$

In addition, the "SHALLOW DIAGONALS" of Pascal's triangle sum to FIBONACCI NUMBERS,

$$\begin{aligned} \sum_{k=1}^{n} \binom{k}{n-k} &= \frac{(-1)^n\ {}_3F_2\left(1,\ 2,\ 1-n;\ \tfrac{1}{2}(3-n),\ 2-\tfrac{1}{2}n;\ -4\right)}{\pi(2-3n+n^2)} \\ &= F_{n+1}, \end{aligned} \tag{3}$$

where ${}_3F_2(a,b,c;\ d,e;\ z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION.

Pascal's triangle contains the FIGURATE NUMBERS along its diagonals. It can be shown that

$$\sum_{i=1}^{n} a_{ij} = \frac{n+1}{j+1}\, a_{nj} = a_{(n+1),(j+1)} \tag{4}$$

and

$$\binom{m+1}{1}\sum k^m + \binom{m+1}{2}\sum k^{m-1} + \ldots + \binom{m+1}{m}\sum k = (n+1)[(n+1)^m - 1]. \tag{5}$$

The "shallow diagonals" sum to the FIBONACCI SEQUENCE, i.e.,

$$\begin{aligned} 1 &= 1 \\ 1 &= 1 \\ 2 &= 1+1 \\ 3 &= 2+1 \\ 5 &= 1+3+1 \\ 8 &= 3+4+1. \end{aligned} \tag{6}$$

In addition,

$$\sum_{j=1}^{i} a_{ij} = 2^i - 1. \tag{7}$$

It is also true that the first number after the 1 in each row divides all other numbers in that row IFF it is a PRIME. If P_n is the number of ODD terms in the first n rows of the Pascal triangle, then

$$0.812\ldots < P_n n^{-\ln 2/\ln 3} < 1 \qquad (8)$$

(Harborth 1976, Le Lionnais 1983).

The BINOMIAL COEFFICIENT $\binom{m}{n}$ mod 2 can be computed using the XOR operation n XOR m, making Pascal's triangle mod 2 very easy to construct. Pascal's triangle is unexpectedly connected with the construction of regular POLYGONS and with the SIERPINSKI SIEVE (Guy 1990).

Starting at row 210, the numbers

$$120 = \binom{10}{3} = \binom{10}{7} = \binom{16}{2} = \binom{16}{14} = \binom{120}{1} = \binom{120}{119} \qquad (9)$$

$$210 = \binom{10}{4} = \binom{10}{6} = \binom{21}{2} = \binom{21}{19} = \binom{210}{1} = \binom{210}{209} \qquad (10)$$

$$3003 = \binom{14}{6} = \binom{14}{8} = \binom{15}{5} = \binom{15}{10} = \binom{78}{2} = \binom{78}{76} \qquad (11)$$

have appeared six times, more than any other number (excluding 1), and remain the most common numbers in the triangle up to at least row 1436.

Guy (1990) gives another several unexpected properties of Pascal's triangle.

Pasch's Axiom

In the plane, if a line intersects one side of a TRIANGLE and misses the three VERTICES, then it must intersect one of the other two sides. This is a special case of the generalized MENELAUS' THEOREM with $n = 3$.

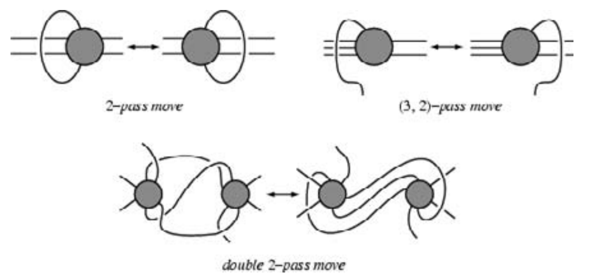
See also HELLY'S THEOREM, MENELAUS' THEOREM, PASCH'S THEOREM

Pasch's Theorem

A theorem stated in 1882 which cannot be derived from EUCLID'S POSTULATES. Given points a, b, c, and d on a LINE, if it is known that the points are ordered as (a, b, c) and (b, c, d), then it is also true that (a, b, d).

See also EUCLID'S POSTULATES, LINE, PASCH'S AXIOM

Pass Equivalent



Two KNOTS are pass equivalent if there exists a sequence of pass moves taking one to the other. Every KNOT is either pass equivalent to the UNKNOT or TREFOIL KNOT. These two knots are not pass equivalent to each other, but the ENANTIOMERS of the TREFOIL KNOT are pass equivalent. A KNOT has ARF INVARIANT 0 if the KNOT is pass equivalent to the UNKNOT and 1 if it is pass equivalent to the TREFOIL KNOT.

Patch

A patch (also called a LOCAL SURFACE) is a differentiable mapping $\mathbf{x}: U \to \mathbb{R}^n$, where U is an open subset of $\mathbb{R}^2$. More generally, if A is any SUBSET of $\mathbb{R}^2$, then a map $\mathbf{x}: A \to \mathbb{R}^n$ is a patch provided that $\mathbf{x}$ can be extended to a differentiable map from U into $\mathbb{R}^n$, where U is an open set containing A. Here, $\mathbf{x}(U)$ (or more generally, $\mathbf{x}(A)$) is called the TRACE of $\mathbf{x}$.

Path

A path γ is a continuous mapping $\gamma: [a, b] \mapsto \mathbb{C}$, where $\gamma(a)$ is the initial point and $\gamma(b)$ is the final point. It is often written parametrically as $\sigma(t)$.

See also CHAIN (GRAPH), CONTOUR, CURVE, EULERIAN CIRCUIT, GRAPH CYCLE, HAMILTONIAN CIRCUIT, UNICURSAL CIRCUIT

Path Graph

The path P_n is a TREE with two nodes of VERTEX DEGREE 1, and the other $n-2$ nodes of VERTEX DEGREE 2. Path graphs P_n are always GRACEFUL for $n > 4$.

See also CHAIN (GRAPH), GRACEFUL GRAPH, HAMILTONIAN PATH, TREE

Path Integral

Let γ be a PATH given parametrically by $\sigma(t)$. Let s denote ARC LENGTH from the initial point. Then

$$\int_\gamma f(s)\,ds = \int_\gamma f(\sigma(t))|\sigma'(t)|\,dt$$
$$= \int_\gamma f(x(t),\ y(t),\ z(t))|\sigma'(t)|\,dt.$$

Path Length

EXTERNAL PATH LENGTH, INTERNAL PATH LENGTH

Path-Connected

See also ARCWISE-CONNECTED, CONNECTED SET, LOCALLY PATHWISE-CONNECTED, PATHWISE-CONNECTED

Path-Connected Set

See also ARCWISE-CONNECTED SET, CONNECTED SET

Pathwise-Connected

A TOPOLOGICAL SPACE X is pathwise-connected IFF for every two points $x, y \in X$, there is a CONTINUOUS FUNCTION f from [0,1] to X such that $f(0) = x$ and $f(1) = y$. Roughly speaking, a SPACE X is pathwise-connected if, for every two points in X, there is a path

connecting them. For LOCALLY PATHWISE-CONNECTED SPACES (which include most "interesting spaces" such as MANIFOLDS and CW-COMPLEXES), being CONNECTED and being pathwise-connected are equivalent, although there are connected spaces which are not pathwise connected. Pathwise-connected spaces are also called 0-connected.

See also CONNECTED SPACE, CW-COMPLEX, LOCALLY PATHWISE-CONNECTED, PATH-CONNECTED, TOPOLOGICAL SPACE

Patriarchal Cross

GAULLIST CROSS

Patterson Quadrature

GAUSS-KRONROD QUADRATURE

Pauli Matrices

Matrices which arise in Pauli's treatment of spin in quantum mechanics. They are defined by

$$\sigma_1 = \sigma_x \equiv \mathsf{P}_1 \equiv \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad (1)$$

$$\sigma_2 = \sigma_y \equiv \mathsf{P}_2 \equiv \begin{bmatrix} 0 & i \\ -i & 0 \end{bmatrix} \quad (2)$$

$$\sigma_3 = \sigma_z \equiv \mathsf{P}_3 \equiv \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \quad (3)$$

The Pauli matrices plus the 2×2 IDENTITY MATRIX I form a complete set, so any 2×2 matrix A can be expressed as

$$\mathsf{A} = c_0 \mathsf{I} + c_1 \sigma_1 + c_2 \sigma_2 + c_3 \sigma_3. \quad (4)$$

The associated matrices

$$\sigma_+ \equiv 2 \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \quad (5)$$

$$\sigma_- \equiv 2 \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \quad (6)$$

$$\sigma^2 \equiv 3 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad (7)$$

can also be defined. The Pauli spin matrices satisfy the identities

$$\sigma_i \sigma_j = \mathsf{I}\delta_{ij} + \epsilon_{ijk} i \sigma_k \quad (8)$$

$$\sigma_i \sigma_j = \sigma_j \sigma_i = 2\sigma_{ij} \quad (9)$$

$$\sigma_x p_x + \sigma_y p_y + \sigma_z p_z = \sqrt{p_x^2 + p_y^2 + p_z^2}. \quad (10)$$

Pauli Spin Matrices

PAULI MATRICES

Payoff Matrix

An $m \times n$ MATRIX which gives the possible outcome of a two-person ZERO-SUM GAME when player A has m possible moves and player B n moves. The analysis of the MATRIX in order to determine optimal strategies is the aim of GAME THEORY. The so-called "augmented" payoff matrix is defined as follows:

$$\mathsf{G} = \begin{bmatrix} P_0 & P_1 & P_2 & \dots & P_n & P_{n+1} & P_{n+2} & \dots & P_{n+m} \\ 0 & 1 & 1 & \dots & 0 & 0 & 0 & \dots & 0 \\ -1 & a_{11} & a_{12} & \dots & a_{1n} & 1 & 0 & \dots & 0 \\ -1 & a_{21} & a_{22} & \dots & a_{2n} & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ -1 & a_{m1} & a_{m2} & \dots & a_{mn} & 0 & 0 & \dots & 1 \end{bmatrix}.$$

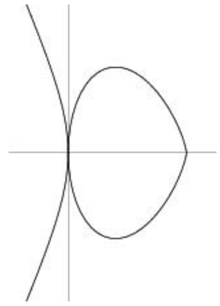
Peano's Axioms

1. Zero is a number.
2. If a is a number, the successor of a is a number.
3. ZERO is not the successor of a number.
4. Two numbers of which the successors are equal are themselves equal.
5. (INDUCTION AXIOM.) If a set S of numbers contains ZERO and also the successor of every number in S, then every number is in S.

Peano's axioms are the basis for the version of NUMBER THEORY known as PEANO ARITHMETIC.

See also INDUCTION AXIOM, PEANO ARITHMETIC

Pear Curve

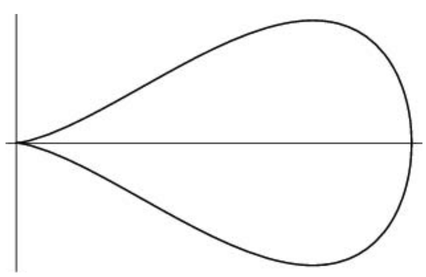


The LEMNISCATE L_3 in the iteration towards the MANDELBROT SET. In CARTESIAN COORDINATES with a constant r, the equation is given by

$$\begin{aligned} r^2 = (x^2+y^2)(1 &+ 2x + 5x^2 + 6x^3 + 6x^4 + 4x^5 + x^6 \\ &- 3y^2 - 2xy^2 + 8x^2y^2 + 8x^3y^2 + 3x^4y^2 + 2y^4 \\ &+ 4xy^4 + 3x^2y^4 + y^6). \end{aligned}$$

See also PEAR-SHAPED CURVE

Pearls of Sluze



$$y^m = kx^n(a-x)^b.$$

The curves with integer n, b, and m were studied by de Sluze between 1657 and 1698. The name "Pearls of Sluze" was given to these curves by Blaise Pascal (MacTutor Archive).

References

MacTutor History of Mathematics Archive. "Pearls of Sluze." http://www-groups.dcs.st-and.ac.uk/~history/Curves/Pearls.html.

Pear-Shaped Curve

A curve given by the Cartesian equation

$$b^2y^2 = x^3(a-x).$$

See also PEAR CURVE, TEARDROP CURVE

References

MacTutor History of Mathematics Archive. "Pear-Shaped Cubic." http://www-groups.dcs.st-and.ac.uk/~history/Curves/Pearshaped.html.

Pearson Kurtosis

Let μ_4 be the fourth CENTRAL MOMENT of random variable and μ_2 its second CENTRAL MOMENT (i.e., the VARIANCE). Then the Pearson kurtosis is defined by

$$\beta_2 \equiv \frac{\mu_4}{\mu_2^2}.$$

See also CENTRAL MOMENT, FISHER KURTOSIS, KURTOSIS

Pearson Mode Skewness

Given a STATISTICAL DISTRIBUTION with measured MEAN, MODE, and STANDARD DEVIATION s, the Pearson mode skewness is

$$\frac{\text{mean} - \text{mode}}{s}.$$

See also MEAN, MODE, PEARSON SKEWNESS, PEARSON'S SKEWNESS COEFFICIENTS, SKEWNESS

Pearson Skewness

Let a STATISTICAL DISTRIBUTION have third MOMENT μ_3 and STANDARD DEVIATION σ, then the Pearson skewness is defined by

$$\beta_1 = \left(\frac{\mu_3}{\sigma^3}\right)^2.$$

See also FISHER SKEWNESS, PEARSON'S SKEWNESS COEFFICIENTS, SKEWNESS

Pearson System

A system of equation types obtained by generalizing the differential equation for the GAUSSIAN DISTRIBUTION

$$\frac{dy}{dx} = \frac{y(m-x)}{a}, \tag{1}$$

which has solution

$$y = Ce^{(2m-x)x/(2a)}, \tag{2}$$

to

$$\frac{dy}{dx} = \frac{y(m-x)}{a+bx+cx^2}, \tag{3}$$

which has solution

$$y = C\left(a+bx+cx^2\right)^{-1/(2c)} \times \exp\left[\frac{(b+2cm)\tan^{-1}\left(\frac{b+2cx}{\sqrt{4ac-b^2}}\right)}{c\sqrt{4ac-b^2}}\right]. \tag{4}$$

Let c_1, c_2 be the roots of $a+bx+cx^2$. Then the possible types of curves are

0. $b = c = 0$, $a > 0$. E.g., NORMAL DISTRIBUTION.
I. $b^2/4ac < 0$, $c_1 \le x \le c_2$. E.g., BETA DISTRIBUTION.
II. $b^2/4ac = 0$, $c < 0$, $-c_1 \le x \le c_1$ where $c_1 \equiv \sqrt{-c/a}$.
III. $b^2/4ac = \infty$, $c = 0$, $c_1 \le x < \infty$ where $c_1 \equiv -a/b$. E.g., GAMMA DISTRIBUTION. This case is intermediate to cases I and VI.
IV. $0 < b^2/4ac < 1$, $-\infty < x < \infty$.
V. $b^2/4ac = 1$, $c_1 \le x < \infty$ where $c_1 \equiv -b/2a$. Intermediate to cases IV and VI.
VI. $b^2/4ac > 1$, $c_1 \le x < \infty$ where c_1 is the larger root. E.g., BETA PRIME DISTRIBUTION.
VII. $b^2/4ac = 0, c > 0, -\infty < x < \infty$. E.g., STUDENT'S T-DISTRIBUTION.

Classes IX-XII are discussed in Pearson (1916). See also Craig (in Kenney and Keeping 1951).

If a Pearson curve possesses a MODE, it will be at $x = m$. Let $y(x) = 0$ at c_1 and c_2, where these may be $-\infty$ or ∞. If yx^{r+2} also vanishes at c_1, c_2, then the rth MOMENT and $(r+1)$th MOMENTS exist.

$$\int_{c_1}^{c_2} \frac{dy}{dx}\left(ax^r + bx^{r+1} + cx^{r+2}\right) dx$$
$$= \int_{c_1}^{c_2} y\left(mx^r - x^{r+1}\right) dx, \tag{5}$$

giving

$$\left[y\left(ax^r + bx^{r+1} + cx^{r+2}\right)\right]_{c_1}^{c_2} - \int_{c_1}^{c_2} y\left[arx^{r-1} + b(r+1)x^r + c(r+2)x^{r+1}\right] dx$$
$$= \int_{c_1}^{c_2} y(mx^r - x^{r+1})\, dx \tag{6}$$

$$0 - \int_{c_1}^{c_2} y\left[arx^{r-1} + b(r+1)x^r + c(r+2)x^{r+1}\right] dx$$
$$= \int_{c_1}^{c_2} y\left(mx^r - x^{r+1}\right) dx. \tag{7}$$

Now define the raw rth moment by

$$\nu_r = \int_{c_1}^{c_2} yx^r\, dx, \tag{8}$$

so combining (7) with (8) gives

$$ar\nu_{r-1} + b(r+1)\nu_r + c(r+2)\nu_{r+1} = -m\nu_r + \nu_{r+1}. \tag{9}$$

For $r = 0$,

$$b + 2c\nu_1 = -m + \nu_1, \tag{10}$$

so

$$\nu_1 = \frac{m+b}{1-2c}, \tag{11}$$

and for $r = 1$,

$$a + 2b\nu_1 + 3c\nu_2 = -m\nu_1 + \nu_2, \tag{12}$$

so

$$\nu_2 = \frac{a + (m+2b)\nu_1}{1-3c}. \tag{13}$$

Combining (11), (13), and the definitions

$$\nu_1 = 0 \tag{14}$$

$$\nu_2 = \mu_2 = 1 \tag{15}$$

obtained by letting $t \equiv (x - \nu_1)/\sigma$ and solving simultaneously gives $b = -m$ and $a = 1 - 3c$. Writing

$$\alpha_r = \mu_r = \nu_r \tag{16}$$

then allows the general recurrence to be written

$$(1-3c)r\alpha_{r-1} - mr\alpha_r + [c(r+2) - 1]\alpha_{r+1} = 0. \tag{17}$$

For the special cases $r = 2$ and $r = 3$, this gives

$$2m + (1-4c)\alpha_3 = 0. \tag{18}$$

$$3(1-3c) - 3m\alpha_3 - (1-5c)\alpha_4 = 0, \tag{19}$$

so the SKEWNESS and KURTOSIS are

$$\gamma_1 = \alpha_3 = \frac{2m}{4c-1} \tag{20}$$

$$\gamma_2 = \alpha_4 - 3 = \frac{6(m^2 - 4c^2 + c)}{(4c-1)(5c-1)}. \tag{21}$$

The parameters a, b, and c can therefore be written

$$a = 1 - 3c \tag{22}$$

$$b = -m = \frac{\gamma_1}{2(1+2\delta)} \tag{23}$$

$$c = \frac{\delta}{2(1+2\delta)}, \tag{24}$$

where

$$\delta \equiv \frac{2\gamma_2 - 3\gamma_1^2}{\gamma_2 + 6}. \tag{25}$$

Pearson Type III Distribution

A skewed distribution which is similar to the BINOMIAL DISTRIBUTION when $p \ne q$ (Abramowitz and Stegun 1972, p. 930).

$$y = k(t + A)^{A^2-1} e^{-At}, \quad (1)$$

for $t \in [0, \infty)$ where

$$A \equiv 2/\gamma \quad (2)$$

$$K \equiv \frac{A^{A^2} e^{-A^2}}{\Gamma(A^2)}, \quad (3)$$

$\Gamma(z)$ is the GAMMA FUNCTION, and t is a standardized variate. Another form is

$$P(x) = \frac{1}{\beta\Gamma(p)} \left(\frac{x-\alpha}{\beta}\right)^{p-1} \exp\left(-\frac{x-\alpha}{\beta}\right). \quad (4)$$

For this distribution, the CHARACTERISTIC FUNCTION is

$$\phi(t) = e^{i\alpha t}(1 - i\beta t)^{-p}, \quad (5)$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \alpha + p\beta \quad (6)$$

$$\sigma^2 = p\beta^2 \quad (7)$$

$$\gamma_1 = \frac{2}{\sqrt{p}} \quad (8)$$

$$\gamma_2 = \frac{6}{p}. \quad (9)$$

Peaucellier Cell

PEAUCELLIER INVERSOR

Peaucellier Inversor

A LINKAGE with six rods which draws the inverse of a given curve. When a pencil is placed at P, the inverse is drawn at P' (or vice versa). If a seventh rod (dashed) is added (with an additional pivot), P is kept on a circle and the locus traced out by P' is a straight line. It therefore converts circular motion to linear motion without sliding, and was discovered in 1864. Another LINKAGE which performs this feat using hinged squares had been published by Sarrus

in 1853 but ignored. Coxeter (1969, p. 428) shows that

$$OP \times OP' = OA^2 - PA^2.$$

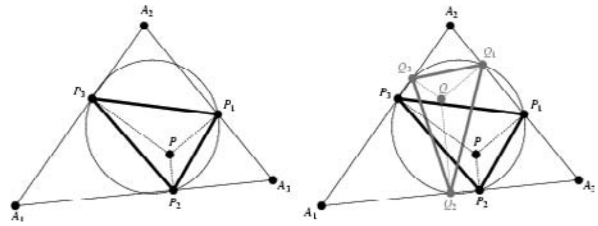
Pedal

PEDAL CURVE

Pedal-Cevian Point

If the PEDAL TRIANGLE of a point P in a TRIANGLE ΔABC is a CEVIAN TRIANGLE, then the point P is called the pedal-cevian point of ΔABC with respect to the PEDAL TRIANGLE.



The CIRCUMCENTER O, ORTHOCENTER H, and INCENTER I of a triangle $\Delta A_1A_2A_3$ are always pedal-Cevian points, with corresponding pedal triangles given by the MEDIAL TRIANGLE $\Delta M_1M_2M_3$, ORTHIC TRIANGLE $\Delta H_1H_2H_3$, and CONTACT TRIANGLE $\Delta T_1T_2T_3$, respectively, and PEDAL POINTS the CENTROID G, ORTHOCENTER H, and GERGONNE POINT Ge, respectively (Honsberger 1995, p. 142). If P is a pedal-Cevian point of a triangle, then so is its ISOTOMIC CONJUGATE POINT Q, as is its reflection P' in the CIRCUMCENTER (Honsberger 1995, p. 143).

See also CEVIAN, CEVIAN TRIANGLE, PEDAL POINT, PEDAL TRIANGLE

References

Honsberger, R. *Episodes in Nineteenth and Twentieth Century Euclidean Geometry.* Washington, DC: Math. Assoc. Amer., pp. 142–143, 1995.

Pedal Circle

The pedal circle with respect to a PEDAL POINT P of a TRIANGLE $\Delta A_1A_2A_3$ is the CIRCUMCIRCLE of the PEDAL TRIANGLE $\Delta P_1P_2P_3$ with respect to P. Amazingly, the vertices of the PEDAL TRIANGLE $\Delta Q_1Q_2Q_3$ of the ISOGONAL CONJUGATE point Q of P also lie on the same circle (Honsberger 1995). If the PEDAL POINT is taken as the INCENTER, the pedal circle is given by the INCIRCLE.

The radius of the pedal circle of a point P is

$$r = \frac{\overline{A_1P} \cdot \overline{A_2P} \cdot \overline{A_3P}}{2\left(R^2 - \overline{OP}^2\right)}$$

(Johnson 1929, p. 141).

When P is on a side of the TRIANGLE, the line between the two perpendiculars is called the PEDAL LINE. Given four points, no three of which are COLLINEAR, then the four PEDAL CIRCLES of each point for the TRIANGLE formed by the other three have a common point through which the NINE-POINT CIRCLES of the four TRIANGLES pass.

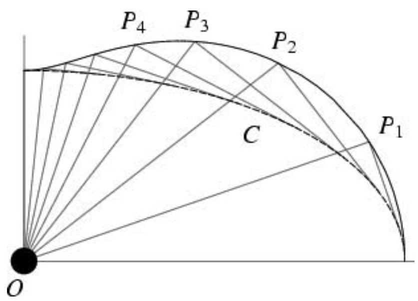
Pedal Coordinates

The pedal coordinates of a point P with respect to the curve C and the PEDAL POINT O are the radial

distance r from O to P and the PERPENDICULAR distance p from O to the line L tangent to C at P.



See also PEDAL CURVE, PEDAL POINT

References

Lawrence, J. D. *A Catalog of Special Plane Curves.* New York: Dover, pp. 2–3, 1972.

Yates, R. C. "Pedal Equations." *A Handbook on Curves and Their Properties.* Ann Arbor, MI: J. W. Edwards, pp. 166–169, 1952.

Pedal Curve

The pedal of a curve C with respect to a point O is the LOCUS of the foot of the PERPENDICULAR from P to the TANGENT to the curve. More precisely, given a curve C, the pedal curve P of C with respect to a fixed point O (called the PEDAL POINT) is the locus of the point P of intersection of the PERPENDICULAR from O to a TANGENT to C. The parametric equations for a curve $(f(t), g(t))$ relative to the PEDAL POINT $(x_0,\ y_0)$ are given by

$$x = \frac{x_0 f'^2 + f g'^2 + (y_0 - g) f' g'}{f'^2 + g'^2}$$

$$y = \frac{g f'^2 + y_0 g'^2 + (x_0 - f) f' g'}{f'^2 + g' 2^2}.$$

When a CLOSED CURVE rolls on a straight line, the AREA between the line and ROULETTE after a complete revolution by any point on the curve is twice the AREA of the pedal curve (taken with respect to the generating point) of the rolling curve.
The following table gives the pedal curves for a number of common special curves.

Curve	PEDAL POINT	Pedal Curve
ASTROID	center	QUADRIFOLIUM
CARDIOID	cusp	CAYLEY'S SEXTIC
CIRCLE	any point	LIMAÇON

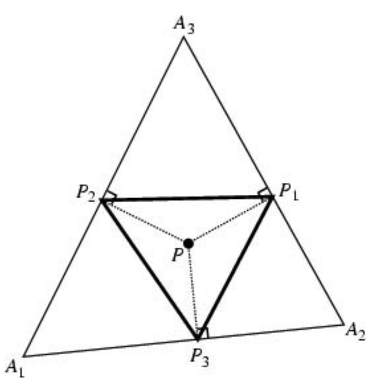
Pedal Line

Mark a point P on a side of a TRIANGLE and draw the perpendiculars from the point to the two other sides.

The line between the feet of these two perpendiculars is called the pedal line.

See also PEDAL TRIANGLE, SIMSON LINE

Pedal Point



The fixed point with respect to which a PEDAL CURVE or PEDAL TRIANGLE is drawn.

See also PEDAL-CEVIAN POINT, PEDAL CURVE, PEDAL TRIANGLE

References

Coxeter, H. S. M. and Greitzer, S. L. *Geometry Revisited.* New York: Random House, p. 22, 1967.

Pedal Triangle

Given a point P, the pedal triangle of P is the TRIANGLE whose VERTICES are the feet of the perpendiculars from P to the side lines. The pedal triangle of a TRIANGLE with TRILINEAR COORDINATES $\alpha : \beta : \gamma$ and angles A, B, and C has VERTICES with TRILINEAR COORDINATES

$$0 : \beta + \alpha \cos C : \gamma + \alpha \cos B \tag{1}$$

$$\alpha + \beta \cos C : 0 : \gamma + \beta \cos A \tag{2}$$

$$\alpha + \gamma \cos B : \beta + \gamma \cos A : 0. \tag{3}$$

The SYMMEDIAN POINT of a triangle is the CENTROID of its pedal triangle (Honsberger 1995, pp. 72–74).
The third pedal triangle is similar to the original one. This theorem can be generalized to: the nth pedal n-gon of any n-gon is similar to the original one. It is also true that

$$P_2P_3 = A_1P \sin \alpha_1 \tag{4}$$

(Johnson 1929, pp. 135–136; Stewart 1940; Coxeter and Greitzer 1967, p. 25). The AREA A of the pedal triangle of a point P is proportional to the POWER of P with respect to the CIRCUMCIRCLE,

$$\begin{aligned} A &= \tfrac{1}{2}\left(R^2 - \overline{OP}^2\right) \sin \alpha_1 \sin \alpha_2 \sin \alpha_3 \\ &= \frac{R^2 - \overline{OP}^2}{4R^2} \Delta \end{aligned} \tag{5}$$

(Johnson 1929, pp. 139–141).

The only closed BILLIARDS path of a single circuit in an ACUTE TRIANGLE is the pedal triangle. There are an infinite number of multiple-circuit paths, but all segments are parallel to the sides of the pedal triangle (Wells 1991).

Peg

The answer to the question "which fits better, a round peg in a square hole, or a square peg in a round hole?" can be interpreted as asking which is larger, the ratio of the AREA of a CIRCLE to its circumscribed SQUARE, or the AREA of the SQUARE to its circumscribed CIRCLE? In 2-D, the ratios are $\pi/4$ and $2/\pi$, respectively. Therefore, a round peg fits better into a square hole than a square peg fits into a round hole (Wells

1986, p. 74).

However, this result is true only in dimensions $n < 9$, and for $n \geq 9$, the unit n-hypersphere fits more closely into the 9-hypercube than vice versa (Singmaster; Wells 1986, p. 74). This can be demonstrated by noting that the formulas for the content $V(n)$ of the unit n-ball, the content $V_c(n)$ of its circumscribed HYPERCUBE, and the content $V_i(n)$ of its inscribed HYPERCUBE are given by

$$V(n) = \frac{\pi^{n/2}}{\Gamma\left(\frac{1}{2}n + 1\right)} \tag{1}$$

$$V_c(n) = 2^n \tag{2}$$

$$V_i(n) = \frac{2^n}{n^{n/2}}. \tag{3}$$

The ratios in question are then

$$R_{\text{round peg}} = \frac{V(n)}{V_c(n)} = \frac{\pi^{n/2}}{2^n \Gamma\left(\frac{1}{2}n + 1\right)} \tag{4}$$

$$R_{\text{square peg}} = \frac{V_i(n)}{V_c(n)} = \frac{2^{\Gamma}\left(\frac{1}{2}n + 1\right)}{n^{n/2}n^{n/2}} \tag{5}$$

(Singmaster 1964). As illustrated above, $R_{\text{round}} < R_{\text{square}}$ only for $n < 9$, with equality at $n \approx 8.13785$.

Peg Knot

CLOVE HITCH

Peg Solitaire

A game played on a cross-shaped board with 33 holes. All holes but the middle one are initially filled with pegs. The goal is to remove all pegs but one by jumping pegs from one side of an occupied peg hole to an empty space, removing the peg which was jumped over. Strategies and symmetries are discussed by Gosper *et al.* (1972). Berlekamp *et al.* (1982) give a complete solution of the puzzle.

A triangular version called HI-Q also exists (Beeler *et al.* 1972, Item 76). Kraitchik (1942) considers a board with one additional hole placed at the vertices of the central right angles.

p-Element

SEMISIMPLE ELEMENT

p-Elementary Subgroup

A p-elementary subgroup of a FINITE GROUP G is a SUBGROUP H which is the GROUP DIRECT PRODUCT

$$H = C_n \times P,$$

where P is a p-GROUP, C_n is a cyclic group, and p does not divide n.

See also GROUP, GROUP DIRECT PRODUCT, INDUCED REPRESENTATION, p-GROUP

Pell Equation

A special case of the quadratic DIOPHANTINE EQUATION having the form

$$x^2 - Dy^2 = 1, \tag{1}$$

where $D > 0$ is a nonsquare NATURAL NUMBER (Dickson 1952). The equation

$$x^2 - Dy^2 = \pm 4 \tag{2}$$

arising in the computation of FUNDAMENTAL UNITS is sometimes also called the Pell equation (Dörrie 1965, Itô 1987), and Dörrie calls the positive form of (2) the FERMAT DIFFERENCE EQUATION. While Fermat deserves credit for being the first to extensively study the equation, the erroneous attribution to Pell was perpetrated by none other than Euler himself (Nagell 1951, p. 197; Dickson 1957, p. 341; Burton 1989). The Pell equation was also solved by the Indian mathematician Bhaskara. Pell equations are extremely important in NUMBER THEORY, and arise in the investigation of numbers which are FIGURATE in more than one way, for example, simultaneously square and triangular.

The equation has an obvious generalization to the Pell-like equation

$$ax^2 \pm by^2 = c, \tag{3}$$

as well as the general second-order bivariate Diophantine equation

$$ax^2 + bxy + cy^2 + dx + ey + f = 0. \tag{4}$$

However, several different technique are required to solve this equation for arbitrary values of a, b, and c. In a future release of *Mathematica*, the command `Reduce` will find solutions to the general equation (4), when they exist.

Pell equations OF THE FORM (1), as well as certain cases of the analogous equation with a minus sign on the right,

$$x^2 - Dy^2 = -1, \tag{5}$$

can be solved by finding the CONTINUED FRACTION $[a_0, a_1, \ldots]$ of $\sqrt{D}$. Note that although the equation (5) is solvable for only certain values of D, the continued fraction technique provides solutions when they exist, and always in the case of (1), for which a solution always exists. A necessary condition that (5) be solvable is that all odd prime factors of D be OF THE FORM $4n+1$, and that D cannot be DOUBLY EVEN (i.e., divisible by 4). However, these conditions are not SUFFICIENT for a solution to exist, as demonstrated by the equation $x^2 - 34y^2 = -1$, which has no solutions in integers (Nagell 1951, pp. 201 and 204).

In all subsequent discussion, ignore the trivial solution $x = 1$, $y = 0$. Let p_n/q_n denote the nth CONVERGENT $[a_0, a_1, \ldots, a_n]$, then we will have solved (1) or (5) if we can find a CONVERGENT which obeys the identity

$$p_n^2 - Dq_n^2 = (-1)^{n+1}. \tag{6}$$

Amazingly, this turns out to *always* be possible as a result of the fact that the CONTINUED FRACTION of a QUADRATIC SURD always becomes periodic at some term a_{r+1}, where $a_{r+1} = 2a_0$, i.e.,

$$\sqrt{D} = [a_0, \overline{a_1, \ldots, a_r, 2a_0}]. \tag{7}$$

To compute the CONTINUED FRACTION convergents to $\sqrt{D}$, use the usual RECURRENCE RELATIONS

$$a_0 = \left\lfloor \sqrt{D} \right\rfloor$$

$$p_0 = a_0 \tag{8}$$

$$p_1 = a_0 a_1 + 1 \tag{9}$$

$$p_n = a_n p_{n-1} + p_{n-2} \tag{10}$$

$$q_0 = 1 \tag{11}$$

$$q_1 = a_1 \tag{12}$$

$$q_n = a_n q_{n-1} + q_{n-2}, \tag{13}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. For reasons to be explained shortly, also compute the two additional quantities P_n and Q_n defined by

$$P_0 = 0 \tag{14}$$

$$P_1 = a_0 \tag{15}$$

$$P_n = a_{n-1} Q_{n-1} - P_{n-1} \tag{16}$$

$$Q_0 = 1 \tag{17}$$

$$Q_1 = D - a_0^2 \tag{18}$$

$$Q_n = \frac{D - P_n^2}{Q_{n-1}} \tag{19}$$

$$a_n = \left\lfloor \frac{a_0 + P_n}{Q_n} \right\rfloor. \tag{20}$$

Now, two important identities satisfied by CONTINUED FRACTION convergents are

$$p_n q_{n-1} - p_{n-1} q_n = (-1)^{n+1} \tag{21}$$

$$p_n^2 - D q_n^2 = (-1)^{n+1} Q_{n+1} \tag{22}$$

(Beiler 1966, p. 262), so both linear

$$ax - by = \pm 1 \tag{23}$$

and quadratic

$$x^2 - Dy^2 = \pm c \tag{24}$$

equations are solved simply by finding an appropriate continued fraction.

Let $a_{r+1} = 2a_0$ be the term at which the continued fraction becomes periodic (which will always happen for a quadratic surd). For the Pell equation

$$x^2 - Dy^2 = 1 \tag{25}$$

with r ODD, $(-1)^{r+1}$ is POSITIVE and the solution in terms of smallest INTEGERS is $x = p_r$ and $y = q_r$, where p_r/q_r is the rth CONVERGENT. If r is EVEN, then $(-1)^{r+1}$ is NEGATIVE, but

$$p_{2r+1}^2 - D q_{2r+1}^2 = 1, \tag{26}$$

so the solution in smallest INTEGERS is $x = p_{2r+1}$, $y = q_{2r+1}$. Summarizing,

$$(x, y) = \begin{cases} (p_r, q_r) & \text{for } r \text{ odd} \\ (p_{2r+1}, p_{2r+1}) & \text{for } r \text{ even.} \end{cases} \tag{27}$$

The equation

$$x^2 - Dy^2 = -1 \tag{28}$$

can be solved analogously to the equation with +1 on the right side IFF r is EVEN, but has no solution if r is odd,

$$(x, y) = \begin{cases} (p_r, q_r) & \text{for } r \text{ even} \\ \text{no solution} & \text{for } r \text{ odd.} \end{cases} \tag{29}$$

Given one solution $(x, y) = (p, q)$ (which can be found as above), a whole family of solutions can be found by taking each side to the nth POWER,

$$x^2 - Dy^2 = (p^2 - Dq^2)^n = 1. \tag{30}$$

Factoring gives

$$\left(x + \sqrt{D}y\right)\left(x - \sqrt{D}y\right) = \left(p + \sqrt{D}q\right)^n \left(p - \sqrt{D}q\right)^n \tag{31}$$

and

$$x + \sqrt{D}y = \left(p + \sqrt{D}q\right)^n \tag{32}$$

$$x - \sqrt{D}y = \left(p - \sqrt{D}q\right)^n, \tag{33}$$

which gives the family of solutions

$$x = \frac{\left(p + q\sqrt{D}\right)^n + \left(p - q\sqrt{D}\right)^n}{2} \tag{34}$$

$$y = \frac{\left(p + q\sqrt{D}\right)^n - \left(p - q\sqrt{D}\right)^n}{2\sqrt{D}}. \tag{35}$$

These solutions also hold for

$$x^2 - Dy^2 = -1, \tag{36}$$

except that n can take on only ODD values.

The following table gives the smallest integer solutions (x, y) to the Pell equation with constant $D \leq 102$ (Beiler 1966, p. 254). SQUARE $D = d^2$ are not included, since they would result in an equation OF THE FORM

$$x^2 - d^2y^2 = x^2 - (dy)^2 = x^2 - y'^2 = 1, \tag{37}$$

which has no solutions (since the difference of two SQUARES cannot be 1).

The first few minimal values of x and y for nonsquare D are 3, 2, 9, 5, 8, 3, 19, 10, 7, 649, ... (Sloane's A033313) and 2, 1, 4, 2, 3, 1, 6, 3, 2, 180, ... (Sloane's A033317), respectively. The values of D having $x = 2$, 3, ... are 3, 2, 15, 6, 35, 12, 7, 5, 11, 30, ... (Sloane's A033314) and the values of D having $y = 1, 2, ...$ are 3, 2, 7, 5, 23, 10, 47, 17, 79, 26, ... (Sloane's A033318). Values of the incrementally largest minimal x are 3, 9, 19, 649, 9801, 24335, 66249, ... (Sloane's A033315) which occur at $D = 2$, 5, 10, 13, 29, 46, 53, 61, 109, 181, ... (Sloane's A033316). Values of the incrementally largest minimal y are 2, 4, 6, 180, 1820, 3588, 9100, 226153980, ... (Sloane's A033319), which occur at $D = 2$, 5, 10, 13, 29, 46, 53, 61, ... (Sloane's A033320).

The more complicated Pell-like equation

$$x^2 - Dy^2 = c \tag{38}$$

with $|c| < \sqrt{D}$ has solution IFF c is one of the values $(-1)^k Q_k$ for $k = 1, 2, ..., r$ computed in the process of finding the convergents to $\sqrt{D}$ (where, as above, $a_{r+1} = 2a_0$ is the term at which the continued fraction becomes periodic). If $|c| > \sqrt{D}$, the procedure is significantly more complicated (Beiler 1966, p. 265; Dickson 1992, pp. 387–388) and is discussed by Gérardin (1910) and Chrystal (1961).

Regardless of how it is found, if a single solution $x = p$, $y = q$ to (38) is known, other solutions can be found. Let p and q be solutions to (38), and r and s solutions to the "unit" form

$$x^2 - Dy^2 = 1. \tag{39}$$

Then the identity

$$\begin{aligned}(p^2 - Dq^2)(r^2 - Ds^2) &= (pr \pm Dqs)^2 - D(ps \pm qr)^2 \\ &= c \end{aligned} \tag{40}$$

allows larger solutions $(x, y) = (pr \pm Dqs, ps \pm qr)$ to the c equation to be found by using incrementally larger values of the (r, s), which can be easily computed using the standard technique for the Pell equation. Such a family of solutions does not necessarily generate *all* solutions, however. For example, the equation

$$x^2 - 10y^2 = 9 \tag{41}$$

has *three* distinct sets of fundamental solutions, $(x, y) = (7, 2)$, (13, 4), and (57, 18). Using (40), these generate the solutions shown in the following table, from which the set of all solutions (7, 2), (13, 4), (57, 18), (253, 80), (487, 154), (2163, 684), (9607, 3038), ... can be generated.

fundamental	generated solutions
(7, 2)	(253, 80), (9607, 3038), (364813, 115364), (13853287, 4380794), ...
(13, 4)	(487, 154), (18493, 5848), (702247, 222070), (26666893, 8432812), ...
(57, 18)	(2163, 684), (82137, 25974), (3119043, 986328), (118441497, 37454490), ...

The case

$$ax^2 - by^2 = c \quad (42)$$

can be reduced to the one above by multiplying through by a,

$$(ax)^2 - (ab)y^2 = ac, \quad (43)$$

finding solutions in $(x' \equiv ax,\ y)$, and then selecting those for which x'/a is an integer.

According to Dickson (1992, pp. 408 and 411), the equation

$$ax^2 + by^2 = c \quad (44)$$

with $a,\ b,\ c > 0$, which has either no solutions or a finite number of solutions, was solved by Gauss (1863) using the METHOD OF EXCLUSIONS and considered by Euler (1773) and Nasimoff (1885), although Euler's methods were incomplete (Dickson 1992, p. 378; Smith 1965). According to Itô (1987), this equation can be solved completely using solutions to Pell's equation. Nasimoff (1885) applied Jacobi elliptic functions to express the number of solutions of this equation for *a, c* ODD (Dickson 1992, p. 411). Additional discussion including the connection with elliptic functions is given in Dickson (1992, pp. 387–391).

The special case of $a = 1$ and c prime was solved by Cornacchia (Cornacchia 1908, Cox 1989, Wagon 1990). Solution for $a = 1$, $b \geq 1$, and odd c is implemented in *Mathematica* as `QuadraticRepresentation[b, c]` in the *Mathematica* add-on package `NumberTheory`NumberTheoryFunctions`` (which can be loaded with the command `<<NumberTheory``). A deterministic algorithm for finding all primitive solutions to (44) for $a,\ b,\ c > 0$ fixed relatively prime integers, $c \geq a + b + 1$, and $(c,\ ab) = 1$ was given by Hardy *et al.* (1990). This algorithm generalizes those of Hermite (1848), Serret (1848), Brillhart (1972), Cornacchia (1908), and Wilker (1980). It requires factorization of c, and has worst case running time of $\mathcal{O}\left(c^{1/4}(\ln c)^3(\ln\ln c))(\ln\ln\ln c\right)$, independent of a and b.

Pell-Lucas Number

PELL NUMBER

Pell-Lucas Polynomial

PELL POLYNOMIAL

Pell Number

The numbers obtained by the U_ns in the LUCAS SEQUENCE with $P = 2$ and $Q = -1$. They and the Pell-Lucas numbers (the V_ns in the LUCAS SEQUENCE) satisfy the RECURRENCE RELATION

$$P_n = 2P_{n-1} + P_{n-2}. \tag{1}$$

Using P_i to denote a Pell number and Q_i to denote a Pell-Lucas number,

$$P_{m+n} = P_m P_{n+1} + P_{m-1} P_n \tag{2}$$

$$P_{m+n} = 2P_m Q_n - (-1)^n P_{m-n}, \tag{3}$$

$$P_{2^t m} = P_m (2Q_m)(2Q_{2m})(2Q_{4m}) \cdots (2Q_{2^{t-1}m}) \tag{4}$$

$$Q_m^2 = 2P_m^2 + (-1)^m \tag{5}$$

$$Q_{2m} = 2Q_m^2 - (-1)^m. \tag{6}$$

The Pell numbers have $P_0 = 0$ and $P_1 = 1$ and are 0, 1, 2, 5, 12, 29, 70, 169, 408, 985, 2378, ... (Sloane's A000129). The Pell-Lucas numbers have $Q_0 = 2$ and $Q_1 = 2$ and are 2, 2, 6, 14, 34, 82, 198, 478, 1154, 2786, 6726, ... (Sloane's A002203).

The only TRIANGULAR Pell number is 1 (McDaniel 1996).

Pell Polynomial

The Pell polynomials $P(x)$ and Lucas-Pell polynomials $Q(x)$ are generated by a LUCAS POLYNOMIAL SEQUENCE using generator $(2x, 1)$. This gives recursive equations for $P(x)$ from $P_0(x) = P_1(x) = 1$ and

$$P_{n+2}(x) = 2xP_{n+1}(x) + P_n(x). \tag{1}$$

The first few are

$$P_1 = 1$$

$$P_2 = 2x$$

$$P_3 = 4x^2 - 1$$

$$P_4 = 8x^3 - 4x$$

$$P_5 = 16x^4 - 12x^2 + 1.$$

The Pell-Lucas numbers are defined recursively by $q_0(x) = 1$, $q_1(x) = x$ and

$$q_{n+2}(x) = 2xq_{n+1}(x) + q_n(x), \tag{2}$$

together with

$$Q_n(x) \equiv 2q_n(x). \tag{3}$$

The first few are

$$Q_1 = 2x$$

$$Q_2 = 4x^2 - 2$$

$$Q_3 = 8x^3 - 6x$$

$$Q_4 = 16x^4 - 16x^2 + 2$$

$$Q_5 = 32x^5 - 40x^3 + 10x.$$

Pell Sequence

PELL NUMBER

Pencil

The set of all LINES through a point. The term was first used by Desargues (Cremona 1960, p. x). The six angles of any pencils of four rays $O\{ABCD\}$ are connected by the relation

$$\sin BOC \sin AOD + \sin COA \sin BOD$$

$$+ \sin AOB \sin COD = 0$$

and the lengths satisfy

$$BC \cdot AD + CA \cdot BD + AB \cdot CD = 0$$

(Lachlan 1893).
Woods (1961) uses the term pencil as a synonym for RANGE, and Altshiller-Court (1979, p. 12) uses the term to mean SHEAF OF PLANES.

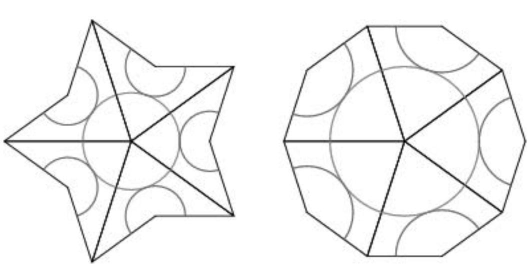
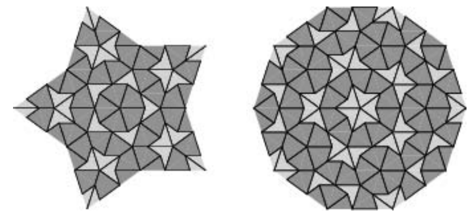
Penrose Tiles



A pair of shapes which tile the plane only aperiodically (when the markings are constrained to match at borders). The two tiles, illustrated above, are called the "KITE" and "DART."



To see how the plane may be tiled aperiodically using the kite and dart, divide the kite into acute and obtuse tiles, shown above. Now define "deflation" and "inflation" operations. The deflation operator takes an acute TRIANGLE to the union of two ACUTE TRIANGLES and one OBTUSE, and the OBTUSE TRIANGLE goes to an ACUTE and an OBTUSE TRIANGLE. These operations are illustrated below.

When applied to a collection of tiles, the deflation operator leads to a more refined collection. The operators do not respect tile boundaries, but do respect the half tiles defined above. There are two ways to obtain aperiodic TILINGS with 5-fold symmetry about a single point. they are known an the "star" and "sun" configurations, and are show below.

Higher order versions can then be obtained by deflation. For example, the following are third-order deflations:

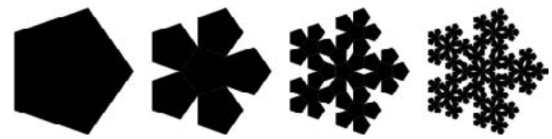
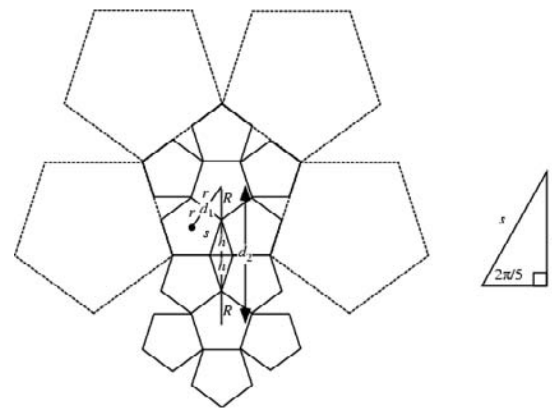
Pentadecagon

A 15-sided POLYGON, sometimes also called the PENTAKAIDECAGON. For a regular pentadecagon with side length 1, the INRADIUS r, CIRCUMRADIUS R, and AREA A are



$$r = \frac{1}{2}\left(\sqrt{3}+\sqrt{5+2\sqrt{5}}\right)$$



$$R = \frac{1}{4}\left(\sqrt{3}+\sqrt{15}+\sqrt{2}\sqrt{5+\sqrt{5}}\right)$$

$$A = \frac{15}{8}\left(\sqrt{3}+\sqrt{15}+\sqrt{2}\sqrt{5+\sqrt{5}}\right).$$

See also POLYGON, REGULAR POLYGON, TRIGONOMETRY VALUES PI/15

Pentaflake

A FRACTAL with 5-fold symmetry. As illustrated above, five PENTAGONS can be arranged around an identical PENTAGON to form the first iteration of the pentaflake. This cluster of six pentagons has the shape of a pentagon with five triangular wedges removed. This construction was first noticed by Albrecht Dürer (Dixon 1991).

For a pentagon of side length 1, the first ring of pentagons has centers at RADIUS

$$d_1 = 2r = \tfrac{1}{2}\left(1+\sqrt{5}\right)R = \phi R, \tag{1}$$

where ϕ is the GOLDEN RATIO. The INRADIUS r and CIRCUMRADIUS R are related by

$$r = R\cos\left(\tfrac{1}{5}\pi\right) = \tfrac{1}{4}\left(\sqrt{5}+1\right)R, \tag{2}$$

and these are related to the side length s by

$$s = 2\sqrt{R^2-r^2} = \tfrac{1}{2}R\sqrt{10-2\sqrt{5}}. \tag{3}$$

The height h is

$$h = s\sin\left(\tfrac{2}{5}\pi\right) = \tfrac{1}{4}s\sqrt{10+2\sqrt{5}} = \tfrac{1}{2}\sqrt{5}R, \tag{4}$$

giving a RADIUS of the second ring as

$$d_2 = 2(R+h) = \left(2+\sqrt{5}\right)R = \phi^3 R. \tag{5}$$

Continuing, the nth pentagon ring is located at

$$d_n = \phi^{2n-1}. \tag{6}$$

Now, the length of the side of the first pentagon compound is given by

$$s_2 = 2\sqrt{(2r+R)^2-(h+R)^2} = R\sqrt{5+2\sqrt{5}}, \tag{7}$$

so the ratio of side lengths of the original pentagon to that of the compound is

$$\frac{s_2}{s} = \frac{R\sqrt{5+2\sqrt{5}}}{\frac{1}{2}R\sqrt{10-2\sqrt{5}}} = 1+\phi. \quad (8)$$

We can now calculate the dimension of the pentaflake fractal. Let N_n be the number of black pentagons and L_n the length of side of a pentagon after the n iteration,

$$N_n = 6^n \quad (9)$$

$$L_n = (1+\phi)^{-n}. \quad (10)$$

The CAPACITY DIMENSION is therefore

$$d_{\text{cap}} = -\lim_{n\to\infty} \frac{\ln N_n}{\ln L_n} = \frac{\ln 6}{\ln(1+\phi)} = \frac{\ln 2 + \ln 3}{\ln(1+\phi)} \quad (11)$$

See also PENTAGON

Pentagon

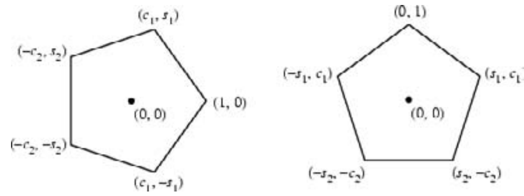
The regular convex 5-gon is called the pentagon. By SIMILAR TRIANGLES in the figure on the left,

$$\frac{d}{1} = \frac{1}{\frac{1}{\phi}} = \phi, \quad (1)$$

where d is the diagonal distance. But the dashed vertical line connecting two nonadjacent VERTICES is the same length as the diagonal one, so

$$\phi = 1 + \frac{1}{\phi} \quad (2)$$

$$\phi^2 - \phi - 1. \quad (3)$$



Solving the QUADRATIC EQUATION gives

$$\frac{1+\sqrt{1+4}}{2}, \quad (4)$$

and taking the plus sign gives the GOLDEN RATIO

$$\phi = \tfrac{1}{2}\left(1+\sqrt{5}\right). \quad (5)$$

(Taking the minus sign instead gives $1/\phi$.)

The coordinates of the VERTICES relative to the center of the pentagon with unit sides are given as shown in the above figure, with

$$c_1 = \cos\left(\frac{2\pi}{5}\right) = \tfrac{1}{4}\left(\sqrt{5}-1\right) \quad (6)$$

$$c_2 = \cos\left(\frac{4\pi}{5}\right) = \tfrac{1}{4}\left(\sqrt{5}+1\right) \quad (7)$$

$$s_1 = \sin\left(\frac{2\pi}{5}\right) = \tfrac{1}{4}\sqrt{10+2\sqrt{5}} \quad (8)$$

$$s_2 = \sin\left(\frac{4\pi}{5}\right) = \tfrac{1}{4}\sqrt{10-2\sqrt{5}}. \quad (9)$$

For a REGULAR POLYGON, the CIRCUMRADIUS, INRADIUS, SAGITTA, and AREA are given by

$$R_n = \tfrac{1}{2}a\csc\left(\frac{\pi}{n}\right) \quad (10)$$

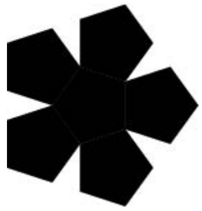
$$r_n = \tfrac{1}{2}a\cot\left(\frac{\pi}{n}\right) \quad (11)$$

$$x_n = R_n - r_n = \tfrac{1}{2}a\tan\left(\frac{\pi}{2n}\right) \quad (12)$$

$$A_n = \tfrac{1}{4}na^2\cot\left(\frac{\pi}{n}\right). \quad (13)$$

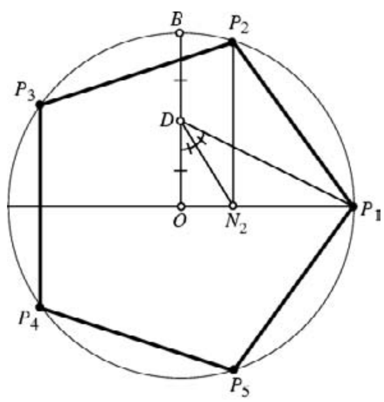
Plugging in $n = 5$ gives

$$R = \tfrac{1}{2}a\,\text{cse}\left(\tfrac{1}{5}\pi\right) = \tfrac{1}{10}a\sqrt{50+10\sqrt{5}} \quad (14)$$



$$r = \tfrac{1}{2}a\cot\left(\tfrac{1}{5}\pi\right) = \tfrac{1}{10}a\sqrt{25+10\sqrt{5}} \quad (15)$$

$$x = \tfrac{1}{2}a\tfrac{1}{10}\sqrt{25-10\sqrt{5}} \quad (16)$$



$$A = \tfrac{1}{4}a^2\sqrt{25+10\sqrt{5}}. \quad (17)$$

Five pentagons can be arranged around an identical pentagon to form the first iteration of the "PENTA-

FLAKE," which itself has the shape of a pentagon with five triangular wedges removed. For a pentagon of side length 1, the first ring of pentagons has centers at radius ϕ, the second ring at ϕ^3, and the nth at ϕ^{2n-1}.

In proposition IV.11, Euclid showed how to inscribe a regular pentagon in a CIRCLE. Ptolemy also gave a RULER and COMPASS construction for the pentagon in his epoch-making work *The Almagest.* While Ptolemy's construction has a SIMPLICITY of 16, a GEOMETRIC CONSTRUCTION using CARLYLE CIRCLES can be made with GEOMETROGRAPHY symbol $2S_1+S_2+8C_1+0C_2+4C_3$, which has SIMPLICITY 15 (De Temple 1991).

pentagon construction

The following elegant construction for the pentagon is due to Richmond (1893). Given a point, a CIRCLE may be constructed of any desired RADIUS, and a DIAMETER drawn through the center. Call the center O, and the right end of the DIAMETER P_1. The DIAMETER PERPENDICULAR to the original DIAMETER may be constructed by finding the PERPENDICULAR BISECTOR. Call the upper endpoint of this PERPENDICULAR DIAMETER B. For the pentagon, find the MIDPOINT of OB and call it D. Draw DP_1, and BISECT $\angle ODP_1$, calling the intersection point with OP_1 N_2. Draw N_2P_2 PARALLEL to OB, and the first two points of the pentagon are P_1 and P_2, and copying the angle $\angle P_1OP_2$ then gives the remaining points P_3, P_4, and P_5 (Coxeter 1969, Wells 1991).

Madachy (1979) illustrates how to construct a pentagon by folding and knotting a strip of paper.

Pentagon Tiling

There are at least 14 classes of convex PENTAGONAL tilings (Steinhaus 1983, p. 75; Wells 1991, pp. 177–179; Pegg), as illustrated above. It has not been proven whether these 14 cases exhaust all possible tilings, but no others are known.

Pentagonal Antiprism

An ANTIPRISM and UNIFORM POLYHEDRON U_{77} whose DUAL POLYHEDRON is the PENTAGONAL DELTAHEDRON.

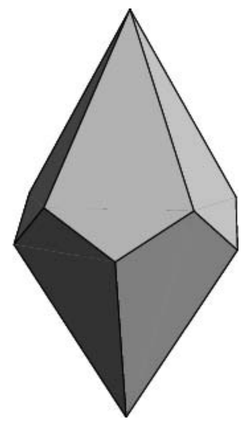
Pentagonal Cupola

JOHNSON SOLID J_5. The bottom 10 VERTICES are

$$\left(\pm\frac{(1+\sqrt{5})\sqrt{5+\sqrt{5}}}{4\sqrt{2}},\ \pm\tfrac{1}{2},\ 0\right),$$

$$\left(\pm\frac{(1+\sqrt{5})\sqrt{5-\sqrt{5}}}{4\sqrt{2}},\ \pm\frac{3+\sqrt{5}}{2},\ 0\right),$$

$$\left(0,\ \pm\tfrac{1}{2}\left(1+\sqrt{5}\right),0\right)$$

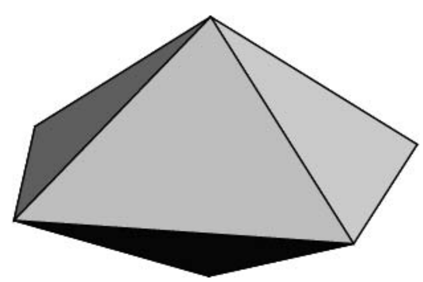


and the top five vertices are

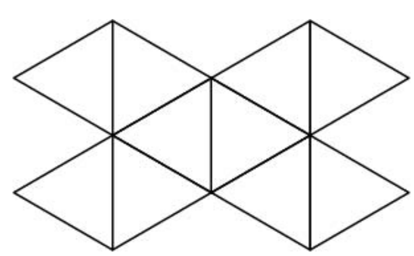
$$\left(\frac{\sqrt{5+\sqrt{5}}}{\sqrt{10}},\ 0,\ \frac{\sqrt{5-\sqrt{5}}}{\sqrt{10}}\right),$$

$$\left(\frac{(\sqrt{5}-1)\sqrt{5+\sqrt{5}}}{4\sqrt{10}},\ \pm\tfrac{1}{4}\left(1+\sqrt{5}\right),\ \frac{\sqrt{5-\sqrt{5}}}{\sqrt{10}}\right),$$

$$\left(\frac{-(\sqrt{5}+1)\sqrt{5+\sqrt{5}}}{4\sqrt{10}},\ \pm\tfrac{1}{2},\ \frac{\sqrt{5-\sqrt{5}}}{\sqrt{10}}\right).$$



Pentagonal Deltahedron



A TRAPEZOHEDRON which is the DUAL POLYHEDRON of the PENTAGONAL ANTIPRISM U_{77}.

See also DUAL POLYHEDRON, PENTAGONAL ANTIPRISM, TRAPEZOHEDRON

Pentagonal Dipyramid

The pentagonal dipyramid is one of the convex DELTAHEDRA, and JOHNSON SOLID J_{13}. It is also the DUAL POLYHEDRON of the PENTAGONAL PRISM U_{76}. The

distance between two adjacent VERTICES on the base of the PENTAGON is

$$d_{12}^2 = \left[1-\cos\left(\tfrac{2}{5}\pi\right)\right]^2 + \sin^2\left(\tfrac{2}{5}\pi\right)$$
$$= \left[1-\tfrac{1}{4}\left(\sqrt{5}-1\right)\right]^2 + \left[\frac{(1+\sqrt{5})\sqrt{5-\sqrt{5}}}{4\sqrt{2}}\right]^2$$
$$= \tfrac{1}{2}\left(5-\sqrt{5}\right), \qquad (1)$$

and the distance between the apex and one of the base points is

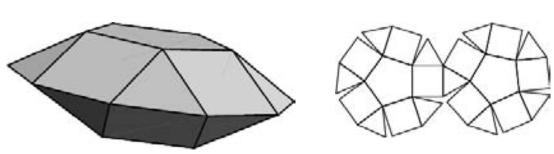
$$d_{1h}^2 = (0-1)^2 + (0-0)^2 + (h-0)^2 = 1+h^2. \qquad (2)$$

But

$$d_{12}^2 = d_{12}^2 \qquad (3)$$
$$\tfrac{1}{2}\left(5-\sqrt{5}\right) = 1+h^2 \qquad (4)$$
$$h^2 = \tfrac{1}{2}\left(3-\sqrt{5}\right), \qquad (5)$$

and

$$h = \sqrt{\frac{3-\sqrt{5}}{2}}. \qquad (6)$$



This root is OF THE FORM $\sqrt{a+b+c}$, so applying SQUARE ROOT simplification gives

$$h = \tfrac{1}{2}\left(\sqrt{5}-1\right) \equiv \phi - 1, \qquad (7)$$

where ϕ is the GOLDEN MEAN.

Pentagonal Number

A POLYGONAL NUMBER OF THE FORM $n(3n-1)/2$. The first few are 1, 5, 12, 22, 35, 51, 70, ... (Sloane's A000326). The GENERATING FUNCTION for the pentagonal numbers is

$$\frac{x(2x+1)}{(1-x)^3} = x + 5x^2 + 12x^3 + 22x^4 + \ldots.$$

Every pentagonal number is 1/3 of a TRIANGULAR NUMBER.

The so-called generalized pentagonal numbers are given by $n(3n-1)/2$ with $n = 0, \pm 1, \pm 2, \ldots$, the first few of which are 0, 1, 2, 5, 7, 12, 15, 22, 26, 35, ... (Sloane's A001318).

Pentagonal Number Theorem

$$\prod_{k=1}^{\infty}(1-x^k) = \sum_{k=-\infty}^{\infty}(-1)^k x^{k(3k+1)/2} \quad (1)$$

$$= 1 + \sum_{k=-1}^{\infty}(-1)^k\left[x^{k(3k-1)/2} + x^{k(3k+1)/2}\right], \quad (2)$$

where $n(3n+1)/2$ are generalized PENTAGONAL NUMBERS. Related equalities are

$$\prod_{k=1}^{\infty}(1-x^k t) = \sum_{n=0}^{\infty}\frac{(-1)^n x^{n(n+1)/2} t^n}{\prod_{k=1}^{n}(1-x^k)} \quad (3)$$

$$\prod_{k=1}^{\infty}(1-x^k t)^{-1} = \sum_{n=0}^{\infty}\frac{t^n}{\prod_{k=1}^{n}(1-x^k)}. \quad (4)$$

A PYRAMID with a PENTAGONAL base. The pentagonal pyramid having equilateral triangles as faces is JOHNSON SOLID J_2. The SLANT HEIGHT of a regular pentagonal pyramid is a special case of the formula for a regular n-gonal PYRAMID with $n = 5$, given by

$$s = \sqrt{h^2 + \tfrac{1}{10}\left(5 + \sqrt{5}\right)a^2}, \qquad (1)$$

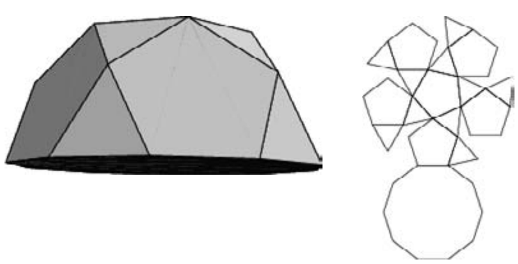
where h is the height and a is the length of a side of the base.

See also Pentagon, Pyramid

Pentagonal Pyramidal Number

A figurate number corresponding to a pentagonal pyramid. The first few are 1, 6, 18, 40, 75, ... (Sloane's A002411). The generating function for the pentagonal pyramidal numbers is

$$\frac{x(2x+1)}{(x-1)^4} = x + 6x^2 + 18x^3 + 40x^4 + \ldots.$$



The odd pentagonal pyramidal numbers are given by 1, 75, 405, 1183, 2601, ... (Sloane's A015223), having squares 1, 5625, 164025, ... (Sloane's A014799), while the even pentagonal pyramidal numbers are given by 6, 18, 40, 126, 196, 288, ... (Sloane's A015224), having squares 36, 324, 1600, 15876, ... (Sloane's A014800).

Pentagonal Rotunda

Half of an icosidodecahedron, denoted R_5. It has 10 triangular and five pentagonal faces separating a pentagonal ceiling and a dodecahedral floor. It is Johnson solid J_6, and the only true rotunda.

See also Icosidodecahedron, Johnson Solid, Rotunda

Pentagonal Square Number

A number which is simultaneously a pentagonal number P_n and a square number S_m. Such numbers exist when

$$\tfrac{1}{2}n(3n-1) = m^2. \quad (1)$$

Completing the square gives

$$\tfrac{1}{2}n(3n-1) = \tfrac{3}{2}\left(n^2 - \tfrac{1}{3}n\right) = \tfrac{3}{2}\left(n - \tfrac{1}{6}\right)^2 - \tfrac{3}{72} = m^2 \quad (2)$$

$$\tfrac{3}{6}(6n-1)^2 - \tfrac{3}{2} = 36m^2 \quad (3)$$

$$(6n-1)^2 - 24m^2 = 1. \quad (4)$$

Substituting $x = 6n - 1$ and $y = 2m$ gives the Pell equation

$$x^2 - 6y^2 = 1, \quad (5)$$

which has solutions $(x, y) = (5, 2)$, (49, 20), (495, 198), ... In terms of (n, m), these give (1,1), (25/3, 10), (81, 99), (2401/3, 980), (7921, 9701), ..., of which the whole number solutions are $(n, m) = (1, 1)$, (81, 99), (7921, 9701), (776161, 950599), ... (Sloane's A046172 and A046173), corresponding to the pentagonal square numbers 1, 9801, 94109401, 903638458801, 8676736387298001, ... (Sloane's A036353).

Rathbun has searched for pentagonal square triangular numbers up to index 2000, but found none other than the trivial number 1.

Pentagonal Triangular Number

A number which is simultaneously a pentagonal number P_n and triangular number T_m. Such numbers exist when

$$\tfrac{1}{2}n(3n-1) = \tfrac{1}{2}m(m+1). \quad (1)$$

Completing the square gives

$$(6n-1)^2 - 3(2m+)^2 = -2. \quad (2)$$

Substituting $x = 6n - 1$ and $y = 2m + 1$ gives the Pell-like quadratic Diophantine equation

$$x^2 - 3y^2 = -2, \quad (3)$$

which has solutions $(x, y) = (5, 3)$, (19, 11), (71, 41), (265, 153), ... In terms of (n, m), these give (1, 1), (10/3,5), (12, 20), (133/3, 76), (165, 285), ..., of which the whole number solutions are $(n, m) = (1, 1)$, (12, 20), (165, 285), (2296, 3976), ... (Sloane's A046174 and A046175), corresponding to the pentagonal triangular numbers 1, 210, 40755, 7906276, 1533776805, ... (Sloane's A014979).

Rathbun has searched for pentagonal square triangular numbers up to index 2000, but found none other than the trivial number 1.

Pentagram

The STAR POLYGON $\{5/2\}$, also called the PENTACLE, PENTALPHA, or PENTANGLE. In the above figure, the pentagram has side length 1, and the indicated lengths are given by

$$a = \sqrt{5} - 2 \tag{1}$$

$$b = \tfrac{1}{2}\left(3 - \sqrt{5}\right) \tag{2}$$

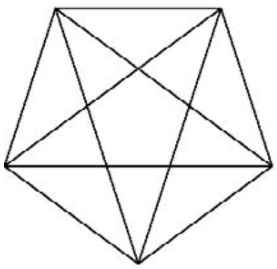
$$r = \tfrac{1}{2} a \cot\left(\frac{\pi}{5}\right) = \tfrac{1}{2}\sqrt{\tfrac{1}{5}\left(5 - 2\sqrt{5}\right)} \tag{3}$$

$$R = \tfrac{1}{2} a \csc\left(\frac{\pi}{5}\right) = \sqrt{\tfrac{1}{10}\left(25 - 11\sqrt{5}\right)} \tag{4}$$

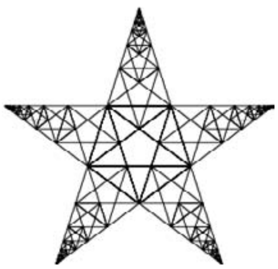
$$h = \sqrt{b^2 - \left(\tfrac{1}{2} a\right)^2} = \tfrac{1}{2}\sqrt{5 - 2\sqrt{5}} \tag{5}$$

$$x = 2(r + h) \sin\left(\frac{\pi}{5}\right) = \tfrac{1}{2}\left(\sqrt{5} - 1\right) \tag{6}$$

$$r' = \sqrt{(h + r)^2 + \left(\tfrac{1}{2} x\right)^2} = \tfrac{1}{2}\sqrt{\tfrac{1}{10}\left(5 + \sqrt{5}\right)} \tag{7}$$



$$y = r' - R = \tfrac{1}{2}\sqrt{\tfrac{1}{2}\left(25 + 11\sqrt{5}\right)} \tag{8}$$



$$L = \sqrt{1 - \tfrac{1}{4} x^2} = \tfrac{1}{2}\sqrt{\tfrac{1}{2}\left(5 + \sqrt{5}\right)}. \tag{9}$$

This gives the ratio

$$\frac{b}{a} = \phi, \tag{10}$$

where ϕ is the GOLDEN RATIO (Wells 1986, p. 36).

A series of embedded pentagrams can be constructed to form a larger pentagram, as illustrated above (Williams 1979, p. 53). If the central pentagram has center (0, 0) and CIRCUMRADIUS 1, then the subsequent pentagrams have radii

$$r_n = \phi^{-n}$$

and centers

$$x_n = -\tfrac{1}{4}(1 - \phi^{-n})\sqrt{50 + 22\sqrt{5}}$$
$$y_n = \tfrac{1}{2}\,\phi(1 - \phi^{-n})$$

modulo rotation by $2\pi k/5$, where ϕ is the GOLDEN RATIO.

Pentagrammic Pyramid

See also PYRAMID

Pentahedral Graph

pentahedral graphs

A POLYHEDRAL GRAPH on five nodes. There are two topologically distinct pentahedral graphs, corresponding to the skeletons of the SQUARE PYRAMID (left figure) and TRIANGULAR DIPYRAMID (right figure). The pentahedral graphs were first enumerated by Steiner (1828; Duijvestijn and Federico 1981).

Pentakaidecagon

PENTADECAGON

Pentakis Dodecahedron

The 60-faced DUAL POLYHEDRON of the TRUNCATED ICOSAHEDRON A_{11} and Wenninger dual W_9. It can be constructed by CUMULATION of a unit edge-length DODECAHEDRON by a pyramid with height $\frac{1}{19}\sqrt{\frac{1}{5}(65+22\sqrt{5})}$. Taking the dual of a TRUNCATED ICOSAHEDRON with unit edge lengths gives a pentakis dodecahedron with edge lengths

$$s_1 = \tfrac{1}{19}\left(18\sqrt{5}-9\right) \tag{1}$$

$$s_2 = \tfrac{3}{2}\left(\sqrt{5}-1\right). \tag{2}$$

Normalizing so that $s_1 = 1$, the SURFACE AREA and VOLUME are

$$S = \tfrac{5}{3}\sqrt{\tfrac{1}{2}\left(421+63\sqrt{5}\right)} \tag{3}$$

$$V = \tfrac{5}{36}\left(41+25\sqrt{5}\right). \tag{4}$$

Pentatope

The simplest regular figure in 4-D, representing the 4-D analog of the solid tetrahedron. It is also called the 5-cell, since it consists of five vertices. The pentatope is the 4-D simplex, and can be viewed as a regular tetrahedron $ABCD$ in which a point E along the fourth dimension through the center of $ABCD$ is chosen so that $EA = EB = EC = ED = AB$. The pentatope has Schläfli symbol {3, 3, 3}. The pentatope is self-dual, has 5 3-D facets (each the shape of a tetrahedron), 10 ridges (faces), 10 edges, and 5 vertices. In the above figure, the pentatope is shown projected onto one of the four mutually perpendicular 3-spaces within the 4-space obtained by dropping one of the four vertex components (R. Towle).

Pentatope Number

A figurate number which is given by

$$Ptop_n = \tfrac{1}{4}\, Te_n(n+3) = \tfrac{1}{24}\, n(n+1)(n+2)(n+3),$$

where Te_n is the nth tetrahedral number. The first few pentatope numbers are 1, 5, 15, 35, 70, 126, ... (Sloane's A000332). The generating function for the pentatope numbers is

$$\frac{x}{(1-x)^5} = x + 5x^2 + 15x^3 + 35x^4 + \ldots.$$

Pentomino

The twelve 5-polyominoes illustrated above and known by the letters of the alphabet they most closely resemble: $f, I, L, N, P, T, U, V, W, X, y, Z$ (Gardner 1960, Golomb 1995). Another common naming convention replaces f, I, L, and N with R, O, Q, and S so that all letters from O to Z are used (Berlekamp *et al.* 1982). In particular, in the life cellular automaton, the f-pentomino is always known as the r-pentomino. The I, L, and T pentominoes can also be called the 5-straight polyomino, L-polyomino, and T-polyomino, respectively.

Pépin's Test

A test for the PRIMALITY of FERMAT NUMBERS $F_n = 2^{2^n} + 1$, with $n \geq 2$ and $k \geq 2$. Then the two following conditions are equivalent:

1. F_n is PRIME and $(k/F_n) = -1$, where (n/k) is the JACOBI SYMBOL,
2. $k^{(F_n-1)/2} \equiv -1 \pmod{F_n}$..

k is usually taken as 3 as a first test.

Per Cent

PERCENT

Per Mil

PERMIL

Per Mille

PERMIL

Percent

The use of percentages is a way of expressing RATIOS in terms of whole numbers. Given a RATIO or FRACTION, it is converted to a percentage by multiplying by 100 and appending a "percentage sign" %. For example, if an investment grows from a number $P = 13.00$ to a number $A = 22.50$, then A is $22.50/13.00 = 1.7308$ times as much as P, or 173.08%, and the investment has grown by 73.08%. A change of a certain percent n is sometimes said to be a change of PERCENTAGE POINTS.

Percolation Theory

bond percolation site percolation

Percolation theory deals with fluid flow (or any other similar process) in random media. If the medium is a set of regular LATTICE POINTS, then there are two types of percolation. A SITE PERCOLATION considers the lattice vertices as the relevant entities; a BOND PERCOLATION considers the lattice edges as the relevant entities.

Weisstein, E. W. "Books about Percolation Theory." http://www.treasure-troves.com/books/PercolationTheory.html.

Percolation Threshold

The critical fraction of lattice points which must be filled to create a continuous path of nearest neighbors from one side to another. The following table is from Stauffer and Aharony (1992, p. 17).

Lattice	Site	Bond
Cubic (Body-Centered)	0.246	0.1803
Cubic (Face-Centered)	0.198	0.119
Cubic (Simple)	0.3116	0.2488
Diamond	0.43	0.388
Honeycomb	0.6962	0.65271
4-Hypercubic	0.197	0.1601
5-Hypercubic	0.141	0.1182
6-Hypercubic	0.107	0.0942
7-Hypercubic	0.089	0.0787
Square	0.592746	0.50000
Triangular	0.50000	0.34729

The square bond value is 1/2 exactly, as is the triangular site. $p_c = 2\sin(\pi/18)$ for the triangular bond and $p_c = 1 - 2\sin(\pi/18)$ for the honeycomb bond. An exact answer for the square site percolation threshold is not known.

Perfect Cuboid

EULER BRICK

Perfect Difference Set

A SET of RESIDUES $\{a_1, a_2, \ldots, a_{k+1}\}$ (mod n) such that every NONZERO RESIDUE can be uniquely expressed in the form $a_i - a_j$. Examples include $\{1, 2, 4\}$ (mod 7) and $\{1, 2, 5, 7\}$ (mod 13). A

NECESSARY condition for a difference set to exist is that n be OF THE FORM k^2+k+1. A SUFFICIENT condition is that k be a PRIME POWER. Perfect sets can be used in the construction of PERFECT RULERS.

See also PERFECT RULER

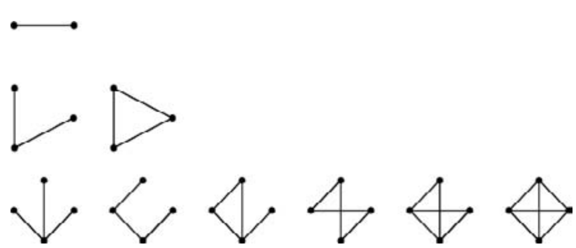
Perfect Digital Invariant



NARCISSISTIC NUMBER

Perfect Graph

A GRAPH G such that for every INDUCED SUBGRAPH of G, the size of the largest CLIQUE equals the CHROMATIC NUMBER. A graph can be tested to see if it is perfect using `PerfectQ[g]` in the *Mathematica* add-on package `DiscreteMath‘Combinatorica‘` (which can be loaded with the command `<<DiscreteMath‘`). Determining if a graph is perfect requires solving two NP-COMPLETE PROBLEMS (Skiena 1990, p. 219).

The numbers of perfect graphs on $n=1$, 2, ... nodes are 1, 2, 4, 11, 33, 148, 906, ... (Sloane's A052431).

The numbers of perfect CONNECTED GRAPHS on $n=1$, 2, ... nodes are 1, 1, 2, 6, 20, 105, 724, ... (Sloane's A052433).

Perfect Information

A class of GAME in which players move alternately and each player is completely informed of previous moves. FINITE, ZERO-SUM, two-player GAMES with perfect information (including checkers and chess) have a SADDLE POINT, and therefore one or more optimal strategies. However, the optimal strategy may be so difficult to compute as to be effectively impossible to determine (as in the game of CHESS).

A perfect magic cube is a MAGIC CUBE for which the CROSS SECTION diagonals, as well as the space diagonals, sum to the MAGIC CONSTANT. Perfect magic cubes are impossible for orders 3 and 4 (Schroeppel 1972, Gardner 1988), but it is not known if such cubes can exist for order 5 or 6 (Wells 1986, p. 72). Although no perfect magic cubes of order five are known, any such cube must have a central value of 63 (Schroeppel 1972; Gardner 1988).

Langman (1962) constructed a perfect magic cube of order seven, and others were found by R. Schroeppel and Ernst Straus (Wells 1986, p. 72). An order-eight perfect magic cube was published anonymously in 1875 (Barnard 1888, Gardner 1976, Benson and Jacoby 1981, Gardner 1988). The construction of such a cube is discussed in Ball and Coxeter (1987). Rosser and Walker rediscovered the order-eight cube in the late 1930s (but did not publish it), and Myers independently discovered the cube illustrated above in 1970 (Wells 1986, p. 72; Gardner 1988). Order 9 and 11 magic cubes have also been discovered, but none of order 10 (Gardner 1988).

Perfect Matching

A MATCHING of a GRAPH containing $n/2$ edges, the largest possible. Not all graphs have a perfect matching, although all graphs do have a *maximal* matching (Skiena 1990, p. 240). Every CUBIC GRAPH without BRIDGES has a perfect matching (Skiena 1990, p. 244).

Perfect Number

Perfect numbers are INTEGERS n such that

$$n = s(n), \tag{1}$$

where $s(n)$ is the RESTRICTED DIVISOR FUNCTION (i.e., the SUM of PROPER DIVISORS of n), or equivalently

$$\sigma(n) = 2n, \tag{2}$$

where $\sigma(n)$ is the DIVISOR FUNCTION (i.e., the SUM of DIVISORS of n including n itself). The first few perfect numbers are 6, 28, 496, 8128, ... (Sloane's A000396). This follows from the fact that

$$6 = 1 + 2 + 3$$

$$28 = 1 + 2 + 4 + 7 + 14$$

$$496 = 1 + 2 + 4 + 8 + 16 + 31 + 62 + 124 + 248,$$

etc. Perfect numbers were deemed to have important numerological properties by the ancients, and were extensively studied by the Greeks, including Euclid.

Perfect numbers are intimately connected with a class of numbers known as MERSENNE PRIMES. This can be demonstrated by considering a perfect number P OF THE FORM $P = q2^{p-1}$ where q is PRIME. Then

$$\sigma(P) = 2P, \tag{3}$$

and using

$$\sigma(q) = q + 1 \tag{4}$$

for q prime, and

$$\sigma(2^{\alpha}) = 2^{\alpha+1} - 1 \tag{5}$$

gives

$$\sigma(q2^{p-1}) = \sigma(q)\sigma(2^{p-1}) = (q+1)(2^p - 1)$$
$$= 2q2^{p-1} = q2^p \quad (6)$$

$$q(2^p - 1) + 2^p - 1 = q2^p \quad (7)$$

$$q = 2^p - 1. \quad (8)$$

Therefore, if $M_p \equiv q = 2^p - 1$ is PRIME, then

$$P = \tfrac{1}{2}(M_p + 1)M_p = 2^{p-1}(2^p - 1) \quad (9)$$

is a perfect number, as was stated in Proposition IX.36 of Euclid's *ELEMENTS* (Dickson 1957, p. 3; Dunham 1990). The first few perfect numbers are summarized in the following table.

#	p	P
1	2	6
2	3	28
3	5	496
4	7	8128
5	13	33550336
6	17	8589869056
7	19	137438691328
8	31	2305843008139952128

While many of Euclid's successors implicitly assumed that *all* perfect numbers were of the form (9) (Dickson 1952, pp. 3–33), the precise statement that all *even* perfect numbers are of this form. This was considered in a 1638 letter from Descartes to Mersenne (Dickson 1957, p. 12), and proving or disproving that Euclid's construction gives all possible even perfect numbers was prosed to Fermat in a 1658 letter from Frans van Schooten (Dickson 1957, p. 14). In a posthumous paper, Euler (Euler 1849) provided the first proof that Euclid's construction gives all possible even perfect numbers (Dickson 1957, p. 19).

It is known that all EVEN perfect numbers (except 6) end in 16, 28, 36, 56, 76, or 96 (Lucas 1891) and have DIGITAL ROOT 1. Every perfect number OF THE FORM $2^p(2^{p+1} - 1)$ can be written

$$2^p(2^{p+1} - 1) = \sum_{k=1}^{p/2} (2k-1)^3. \quad (10)$$

All EVEN perfect numbers $P > 6$ are OF THE FORM

$$P = 1 + 9T_n, \quad (11)$$

where T_n is a TRIANGULAR NUMBER

$$T_n = \tfrac{1}{2} n(n+1) \quad (12)$$

such that $n = 8j + 2$ (Eaton 1995, 1996). In addition, all even perfect numbers are HEXAGONAL NUMBERS, so it follows that perfect numbers are always the sum of consecutive POSITIVE INTEGERS starting at 1, for example,

$$6 = \sum_{n=1}^{3} n \quad (13)$$

$$28 = \sum_{n=1}^{7} n \quad (14)$$

$$496 = \sum_{n=1}^{31} n \quad (15)$$

(Singh 1997).

It is not known if any ODD PERFECT NUMBERS exist, although numbers up to 10^{300} have been checked (Brent *et al.* 1991; Guy 1994, p. 44) without success.

The sum of reciprocals of all the divisors of a perfect number is 2, since

$$\underbrace{n + \ldots + c + b + a}_{n} = 2n \quad (16)$$

$$\frac{n}{a} + \frac{n}{b} + \ldots = 2n \quad (17)$$

$$\frac{1}{a} + \frac{1}{b} + \ldots = 2. \quad (18)$$

If $s(n) > n$, n is said to be an ABUNDANT NUMBER. If $s(n) < n$, n is said to be a DEFICIENT NUMBER. And if $s(n) = kn$ for a POSITIVE INTEGER $k > 1$, n is said to be a MULTIPERFECT NUMBER of order k.

The only even perfect number OF THE FORM $x^3 + 1$ is 28 (Makowski 1962).

Perfect Partition

A PARTITION of n whose elements *uniquely* generate any number 1, 2, ..., n. The following table gives the first several perfect partitions for small n.

n	perfect partitions
1	{1}
2	{1, 1}
3	{2, 1}, {1, 1, 1}
4	{1, 1, 1, 1}
5	{3, 1, 1}, {2, 2, 1}, {1, 1, 1, 1, 1}
6	{1, 1, 1, 1, 1, 1}

The numbers of perfect partitions of n for $n = 1, 2, \ldots$ are given by 1, 1, 2, 1, 3, 1, 4, 2, 3, ... (Sloane's A002033). For p^k a PRIME POWER, the number of perfect partitions $a(p^k)$ is given by

$$a(p^k) = 2^{k-1}.$$

Let $b(n) = a(n+1)$, then $b(n)$ is given by the RECURRENCE RELATION

$$b(n) = \sum_{\substack{d \mid n \\ d \neq n}} b(d).$$

The number of perfect partitions of n is equal to the number of ordered factorizations of $n+1$ (Goulden and Jackson 1983, p. 94).

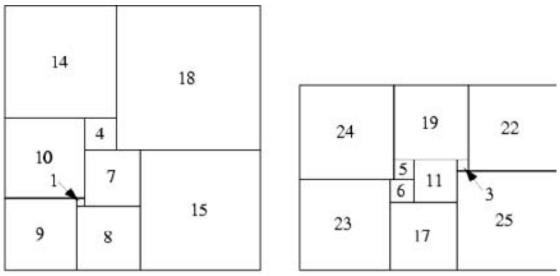
Perfect Proportion

Since

$$\frac{2a}{a+b} = \frac{2ab}{(a+b)b}, \tag{1}$$

it follows that

$$\frac{a}{\frac{a+b}{2}} = \frac{\frac{2ab}{a+b}}{b}, \tag{2}$$



so

$$\frac{a}{A} = \frac{H}{b}, \tag{3}$$

where A and H are the ARITHMETIC MEAN and HARMONIC MEAN of a and b. This relationship was purportedly discovered by Pythagoras.

See also ARITHMETIC MEAN, HARMONIC MEAN

Perfect Rectangle

9 *square rectangle* 10 *square rectangle*

A RECTANGLE which cannot be built up of SQUARES all of different sizes is called an imperfect rectangle. A RECTANGLE which can be built up of SQUARES all of different sizes is called perfect. The number of perfect rectangles of orders 8, 9, 10, ... are 0, 2, 6, 22, 67, 213, 744, 2609, ... (Sloane's A002839) and the corresponding numbers of imperfect rectangles are 0, 1, 0, 0, 9, 34, 103, 283, ... (Sloane's A002882).

Perfect Ruler

A type of RULER considered by Guy (1994) which has k distinct marks spaced such that the distances between marks can be used to measure all the distances 1, 2, 3, 4, ... up to some maximum distance $n > k$. Such a ruler can be constructed from a PERFECT DIFFERENCE SET by subtracting one from each element. For example, the PERFECT DIFFERENCE SET $\{1, 2, 5, 7\}$ gives 0, 1, 4, 6, which can be used to measure $1-0=1$, $6-4=2$, $4-1=3$, $4-0=4$, $6-1=5$, $6-0=6$ (so we get 6 distances with only four marks).

Perfect Set

A SET P is called perfect if $P = P'$, where P' is the DERIVED SET of P.

See also DERIVED SET, SET

Perfect Shuffle

Gale (1992) considered the following problem. Take an infinite deck of cards labeled 1, 2, 3, 4, 5, 6, ... At step n, pick up the top n cards and interlace them with the next n cards. This is called a perfect n-shuffle. For example, after step two, we have 3, 2, 4, 1, 5, 6, 7, ... For step there, pick up 3, 2, 4 and shuffle them in, giving 1, 3, 5, 2, 6, 4, 7, 8, 9, ... Iterate this process. It is conjectured that eventually every number appears on top of the deck.

The cards on top of deck at the nth step are 1, 2, 3, 1, 6, 5, 9, 1, 4, 2, 16, 10, 12, ... (Sloane's A035485). The step at which card n first appears on top the deck is given by 0, 1, 2, 8, 5, 4, 78, 37, ... (Sloane's A035490). The position of the first card after the nth shuffle is 1, 2, 4, 1, 2, 4, 8, 1, 2, 4, 8, 16, 7, 14, 28, ... (Sloane's A035492). The order in which new cards appear on top for the first time is 1, 2, 3, 6, 5, 9, 4, 16, 10, ... (Sloane's A035493). The order in which record new high cards appear on top for the first time is 1, 2, 3, 6, 9, 16, ... (Sloane's A035494).

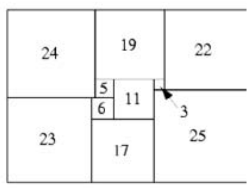
Perfect Square

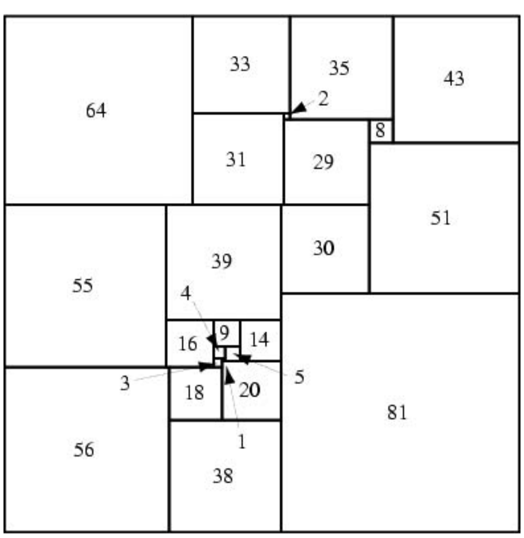
The term perfect square is used to refer to a SQUARE NUMBER, a PERFECT SQUARE DISSECTION, or a factorable quadratic polynomial OF THE FORM $a^2 \pm 2ab + b^2 = (a \pm b)^2$.



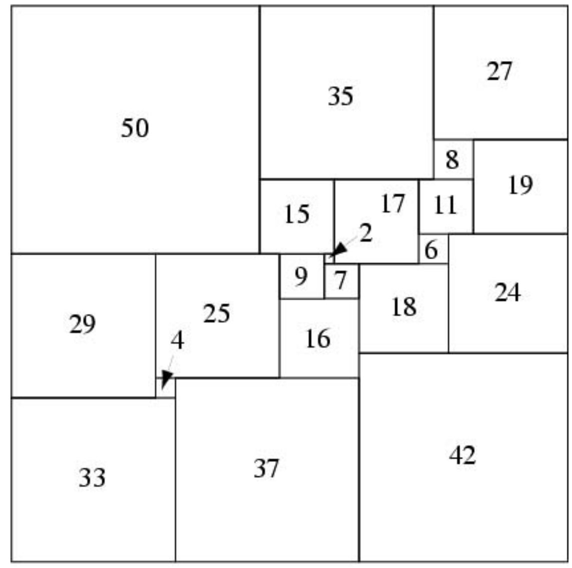
See also PERFECT SQUARE DISSECTION, QUADRATIC EQUATION, SQUARE NUMBER, SQUAREFREE

Perfect Square Dissection

A SQUARE which can be DISSECTED into a number of smaller SQUARES with no two equal is called a PERFECT SQUARE DISSECTION (or a SQUARED SQUARE). Square dissections in which the squares need not be different sizes are called MRS. PERKINS' QUILTS. If no subset of the SQUARES forms a RECTANGLE, then the perfect square is called "simple."



9 *square rectangle*



10 *square rectangle*

Moroz (1925) constructed a 33×32 PERFECT RECTANGLE composed of nine squares of different sizes (Descartes 1971), but Lusin claimed that perfect squares were impossible to construct. This assertion was proved erroneous when a 55-SQUARE perfect square was published by R. Sprague in 1939 (Wells 1991). Reichert and Toepkin (1940) proved that a RECTANGLE cannot be dissected into fewer than nine different SQUARES (Steinhaus 1983, p. 297).

24-*square perfect square*

A 24-SQUARE perfect square was subsequently found by Willcocks (Willcocks 1948, 1951; Steinhaus 1983, pp. 8–9).

21-*square perfect square*

There is a unique simple perfect square of order 21 (the lowest possible order), discovered in 1978 by A. J. W. Duijvestijn (Bouwkamp and Duijvestijn 1992). It is composed of 21 squares with total side length 112, and is illustrated above. There is a simple notation (sometimes called Bouwkamp code) used to describe perfect squares. In this notation, brackets are used to group adjacent squares with flush tops, and then the groups are sequentially placed in the highest (and leftmost) possible slots. For example, the 21-square illustrated above is denoted [50, 35, 27], [8, 19], [15, 17, 11], [6, 24], [29, 25, 9, 2], [7, 18], [16], [42], [4, 37], [33].

A compound 26-perfect square having side length 608 was discovered in 1940 (Brooks *et al.* 1940; Kraitchik 1942, p. 198). Beiler (1966) illustrates a compound 28-square and a simple 38-square. Gardner (1961, pp. 203 and 206) illustrates compound 39- and 24-squares.

The number of simple perfect squares of order n for $n \geq 21$ are 1, 8, 12, 26, 160, 441, ... (Sloane's A006983). Duijvestijn's Table I gives a list of the 441 simple perfect squares of order 26, the smallest with side length 212 and the largest with side length 825. Skinner (1993) gives the smallest possible side length (and smallest order for each) as 110 (22), 112 (21), 120 (24), 139 (22), 140 (23), ... for simple perfect squared squares, and 175 (24), 235 (25), 288 (26), 324 (27), 325 (27), ... for compound perfect squared squares.

There are actually three simple perfect squares having side length 110. They are [60, 50], [23, 27], [24, 22, 14], [7, 16], [8, 6], [12, 15], [13], [2, 28], [26], [4, 21, 3], [18], [17] (order 22; discovered by A. J. W. Duijvestijn); [60, 50], [27, 23], [24, 22, 14],

[4, 19], [8, 6], [3, 12, 16], [9], [2, 28], [26], [21], [1, 18], [17] (order 22; discovered by T. H. Willcocks); and [44, 29, 37], [21, 8], [13, 32], [28, 16], [15, 19], [12,4], [3, 1], [2, 14], [5], [10, 41], [38, 7], [31] (order 23; discovered by A. J. W. Duijvestijn).

D. Sleator has developed an efficient ALGORITHM for finding *non*-simple perfect squares using what he calls rectangle and "ell" grow sequences. This algorithm finds a slew of compound perfect squares of orders 24–32. Weisstein gives a partial list of known simple and compound perfect squares (where the number of simple perfect squares is exact for orders less than 27) as well as *Mathematica* algorithms for drawing them.

Order	# Simple	# Compound
21	1	0
22	8	0

Perfectly Weighted Tree

If G is a weighted tree with weights $w_i > 1$ assigned to each vertex v_i, then G is perfectly weighted if the matrix

$$M_G = \begin{bmatrix} w_1 & 0 & \cdots & 0 \\ 0 & w_2 & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \ddots & w_n \end{bmatrix} - \operatorname{adj}(G),$$

where akj(G) is the ADJACENCY MATRIX of G (Butske *et al.* 1999).

See also ADJACENCY MATRIX

Periapsis

The smallest radial distance of an ELLIPSE as measured from a FOCUS. Taking $v=0$ in the equation of an ELLIPSE

$$r=\frac{a(1-e^2)}{1+e\cos v}$$

gives the periapsis distance

$$r_-=a(1-e).$$

Periapsis for an orbit around the Earth is called perigee, and periapsis for an orbit around the Sun is called perihelion.

See also APOAPSIS, ECCENTRICITY, ELLIPSE, FOCUS

Perigon

An ANGLE of 2π radians $=360^\circ$ corresponding to the CENTRAL ANGLE of an entire CIRCLE.

Perimeter

The ARC LENGTH along the boundary of a closed 2-D region. The perimeter of a CIRCLE is called the CIRCUMFERENCE.

See also CIRCUMFERENCE, CLUSTER PERIMETER, HONEYCOMB CONJECTURE, SEMIPERIMETER

Perimeter Polynomial

A sum over all CLUSTER PERIMETERS.

Period Doubling

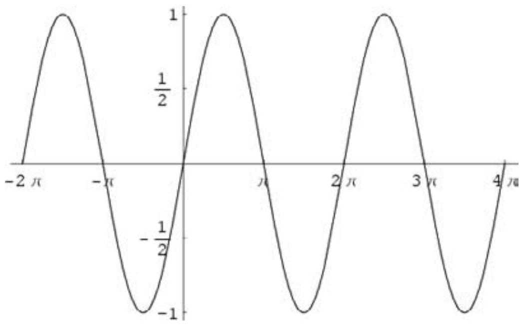
A characteristic of some systems making a transition to CHAOS. Doubling is followed by quadrupling, etc. An example of a map displaying period doubling is the LOGISTIC MAP.

See also CHAOS, LOGISTIC MAP

Period Ratio

HALF-PERIOD RATIO

Period Three Theorem



Li and Yorke (1975) proved that *any* 1-D system which exhibits a regular CYCLE of period three will also display regular CYCLES of every other length as well as completely CHAOTIC CYCLES.

See also CHAOS, CYCLE (MAP)

References

Li, T. Y. and Yorke, J. A. "Period Three Implies Chaos." *Amer. Math. Monthly* **82**, 985–92, 1975.

Periodic Function

A FUNCTION $f(x)$ is said to be periodic with period p if

$$f(x)=f(x+np)$$

for $n=1$, 2, ... For example, the SINE function $\sin x$, illustrated above, is periodic with period 2π (as well as with period -2π, 4π, 6π, etc.).
The CONSTANT FUNCTION $f(x)=0$ is periodic with any period R for all NONZERO REAL NUMBERS R, so there is no concept analogous to the LEAST PERIOD for constant functions.

Periodic Matrix

A SQUARE MATRIX A such that the MATRIX POWER $\mathsf{A}^{k+1}=\mathsf{A}$ for k a positive integer is called a periodic matrix. If k is the least such integer, then the matrix is said to have period k. If $k=1$, then $\mathsf{A}^2=\mathsf{A}$ and A is called IDEMPOTENT.

See also MATRIX POWER

References

Ayres, F. Jr. *Theory and Problems of Matrices.* New York: Schaum, p. 11, 1962.

Periodic Point

A point x_0 is said to be a periodic point of a FUNCTION f of period n if $f^n(x_0)=x_0$, where $f_0(x)=x$ and $f^n(x)$ is defined recursively by $f^n(x)=f(f^{n-1}(x))$.

See also LEAST PERIOD, PERIODIC FUNCTION, PERIODIC SEQUENCE

Periodic Sequence

A SEQUENCE $\{a_i\}$ is said to be periodic with period p with if it satisfies $a_i=a_{i+np}$ for $n=1, 2, \ldots$. For example,

$\{1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, \ldots\}$ is a periodic sequence with LEAST PERIOD 2.

See also EVENTUALLY PERIODIC, PERIODIC FUNCTION, PERIODIC POINT

Periodic Zeta Function

$$F(x, s)=\sum_{m=1}^{\infty}\frac{e^{2\pi imx}}{m^s}$$
$$=\psi_s(e^{2\pi ix}),$$

where $\psi_s(x)$ is the POLYGAMMA FUNCTION.

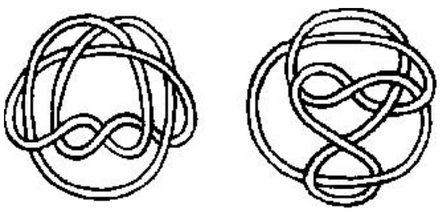
Periodogram

A graphical plot with ABSCISSA given by the number p of consecutive numbers constituting a single period and ORDINATE given by the correlation ratio η. The equation of the periodogram is

$$\eta^2=\frac{\frac{a^2}{2m^2}\sin^2\left(\frac{m\pi p}{T}\right)+\frac{\sigma_b^2}{m}}{\frac{1}{2}a^2+\sigma_b^2},$$

where each of the terms of the sequence u_x consists of a simple periodic part of period T, together with a part which does not involve this periodicity b_x, so

$$u_x=a\sin\left(\frac{2\pi x}{T}\right)+b_x,$$



σ_b is the standard deviation of the bs, σ is the standard deviation of the us, and m is the number of periods covered by the observations.

Perko Pair

The KNOTS 10–161 and 10–162 illustrated above. For many years, they were listed as separate knots in Little (1885) and all similar tables, including the pictorial enumeration of Rolfsen (1976, Appendix C). They were identified as identical by Perko (1974), who found that they are related to one another by the so-called PERKO MOVE (Perko 1974, Hoste *et al.* 1998). Although these knots are equivalent, their diagrams have different WRITHES (Hoste *et al.* 1998).

Permanence of Algebraic Form

All ELEMENTARY FUNCTIONS can be extended to the COMPLEX PLANE. Such definitions agree with the real

definitions on the X-AXIS and constitute an ANALYTIC CONTINUATION.

See also ANALYTIC CONTINUATION, ELEMENTARY FUNCTION, PERMANENCE OF MATHEMATICAL RELATIONS PRINCIPLE

References

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, p. 380, 1985.

Permanence of Mathematical Relations Principle

CONTINUITY PRINCIPLE

Permanent

An analog of a DETERMINANT where all the signs in the expansion by MINORS are taken as POSITIVE. The permanent of a MATRIX **A** is the coefficient of $x_1 \ldots x_n$ in

$$\prod_{i=1}^{n}(a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n)$$

(Vardi 1991). Another equation is the RYSER FORMULA

$$\operatorname{perm}(a_{ij}) = (-1)^n \sum_{a \subseteq \{1,\ \ldots,\ n\}} (-1)^{|s|} \prod_{i=1}^{n} \sum_{j \in s} a_{ij},$$

where the SUM is over all SUBSETS of $\{1,\ \ldots,\ n\}$, and $|s|$ is the number of elements in s (Vardi 1991). Muir (1960, p. 19) uses the notation $|_+|_+$ to denote a permanent. The permanent can be implemented in *Mathematica* as

```
Permanent[m_List]  :=  With[{v  =  Array[x,
Length[m]]},
   Coefficient[Times @@ (m.v), Times @@ v] ]
```

The computation of permanents has been studied fairly extensively in algebraic complexity theory. The complexity of the best-known algorithms grows as the exponent of the matrix size (Knuth 1998, p. 499), which would appear to be very surprising, given the permanent's similarity to the tractable DETERMINANT.

If M is a UNITARY MATRIX, then

$$|\operatorname{perm}(\mathsf{M})| \leq 1$$

(Minc 1978, p. 25; Vardi 1991). The maximum permanent for an $n \times n$ BINARY MATRIX is $n!$, corresponding to all elements 1.

Permil

The use of permil (a.k.a. parts per thousand) is a way of expressing RATIOS in terms of whole numbers. Given a RATIO or FRACTION, it is converted to a permil-age by multiplying by 1000 and appending a "mil sign" %0. For example, if an investment grows from a number $P = 13.00$ to a number $A = 22.50$, then A is $22.50/13.00 = 1.7308$ times as much as P, or 1730.8%0.

See also PERCENT

Permutation

The rearrangement of elements in an ordered list S into a ONE-TO-ONE correspondence with S itself, also called an "arrangement number" or "order." The number of permutations on a set of n elements is given by $n!$ (n FACTORIAL; Uspensky 1937, p. 18). For example, there are $2! = 2 \cdot 1 = 2$ permutations of $\{1,\ 2\}$, namely $\{1,\ 2\}$ and $\{2,\ 1\}$, and $3! = 3 \cdot 2 \cdot 1 = 6$ permutations of $\{1,\ 2,\ 3\}$, namely $\{1,\ 2,\ 3\}$, $\{1,\ 3,\ 2\}$, $\{2,\ 1,\ 3\}$, $\{2,\ 3,\ 1\}$, $\{3,\ 1,\ 2\}$, and $\{3,\ 2,\ 1\}$. The permutations of a list can be found in *Mathematica* using the command `Permutations[`*list*`]`. A list of length n can be tested to see if it is a permutation of 1, ..., n with the command `PermutationQ[`*list*`]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Sedgewick (1977) summarized a number of algorithms for generating permutations, and identifies the minimum change permutation algorithm of Heap (1963) to be generally the fastest (Skiena 1990, p. 10). Another method of enumerating permutations was given by Johnson (1963; Séroul 2000, pp. 213–218).

The number of ways of obtaining an *ordered* subset of k elements from a set of n elements is given by

$$ {}_nP_k \equiv \frac{n!}{(n-k)!} \tag{1}$$

(Uspensky 1937, p. 18). For example, there are $4!/2! = 12$ 2-subsets of {1, 2, 3, 4}, namely {1, 2}, {1, 3}, {1, 4}, {2, 1}, {2, 3}, {2, 4}, {3, 1}, {3, 2}, {3, 4}, {4, 1}, {4, 2}, and {4, 3}. The *unordered* subsets containing k elements are known as the k-SUBSETS of a given set.

A representation of a permutation as a product of CYCLES is unique (up to the ordering of the cycles). An example of a cyclic decomposition is ({1, 3, 4}, {2}), corresponding to the permutations (1 → 3, 3 → 4, 4 → 1) and (2 → 2), which combine to give {4, 2, 1, 3}. Muir (1960, p. 8) uses the notation (1237)(4568) to denote the ordered permutation (12345678), and (1237)(4568) to denote (12374568).

Any permutation is also a product of TRANSPOSITIONS. Permutations are commonly denoted in LEXICOGRAPHIC or TRANSPOSITION ORDER. There is a correspondence between a PERMUTATION and a pair of YOUNG TABLEAUX known as the SCHENSTED CORRESPONDENCE.

The number of wrong permutations of n objects is $[n!/e]$ where $[x]$ is the NINT function. A permutation of n ordered objects in which no object is in its natural place is called a DERANGEMENT (or sometimes, a COMPLETE PERMUTATION) and the number of such permutations is given by the SUBFACTORIAL $!n$.

Using

$$(x+y)^n = \sum_{r=0}^{n} \binom{n}{r} x^{n-r} y^r \tag{2}$$

with $x = y = 1$ gives

$$2^n = \sum_{r=0}^{n} \binom{n}{r}, \tag{3}$$

so the number of ways of choosing 0, 1, ..., or n at a time is 2^n.

The set of all permutations of a set of elements 1, ..., n can be obtained using the following recursive procedure

```
    1  2
    /
 2  1
```
(4)

```
    1     2  3
          /
    1  3  2
    /
 3  1     2
 |
 3  2     1
    \
    2  3  1
          \
    2     1  3
```
(5)

Let the set of INTEGERS 1, 2, ..., n be permuted and the resulting sequence be divided into increasing RUNS. As n approaches INFINITY, the average length of the nth RUN is denoted L_n. The first few values are

$$L_1 = e - 1 = 1.71828818\ldots \tag{6}$$

$$L_2 = e^2 - 2e = 1.9524\ldots \tag{7}$$

$$L_3 = e^3 - 3e^2 + \tfrac{3}{2}e = 1.9957\ldots, \tag{8}$$

where e is the base of the NATURAL LOGARITHM (Knuth 1973, Le Lionnais 1983).

Permutation Graph

For a PERMUTATION α in the SYMMETRIC GROUP S_p, the α-permutation graph of a LABELED GRAPH G is the GRAPH UNION of two disjoint copies of G (say, G_1 and G_2), together with the lines joining point v_i of G_i with $v_{\alpha(i)}$ of G_2 (Harary 1994, p. 175). Skiena (1990, p. 28) defined a permutation graph G_p as a GRAPH whose edges $\{v_i, v_j\}$ correspond exactly to (i, j) being a PERMUTATION INVERSION is some PERMUTATION p, i.e., $i<j$ but j occurs before i in p.

The above graph corresponds to the permutation $\{2, 1, 5, 6, 7, 10, 9, 4, 8, 3\}$, which has PERMUTATION INVERSION $\{2, 1, 10, 8, 3, 4, 5, 9, 7, 6\}$.

Permutation Group

A FINITE GROUP of order $n!$ consisting of substitutions of n elements for each other. For instance, the 24 PERMUTATIONS on four elements form a permutation group, and one the operations in this group is the permutation $\{4, 2, 1, 3\}$, which rearranges the elements $\{A, B, C, D\}$ in the order $\{D, B, A, C\}$. A permutation group of two elements is called a TRANSPOSITION.

Every SUBSTITUTION GROUP with >2 elements can be written as a product of transpositions. For example,

$$(abc) = (ab)(ac)$$

$$(abcde) = (ab)(ac)(ad)(ae).$$

CONJUGACY CLASSES of elements which are interchanged are called CYCLES (in the above example, the CYCLES are $\{\{1, 3, 4\}, \{2\}\}$).

Two PERMUTATIONS form a group only if one is the identity element and the other is an INVOLUTION, i.e., a PERMUTATION which is its own inverse (Skiena 1990, p. 20).

See also CAYLEY'S GROUP THEOREM, CYCLE (PERMUTATION), GROUP, INVOLUTION (PERMUTATION), NETTO'S CONJECTURE, PERMUTATION, SUBSTITUTION GROUP, TRANSPOSITION

Permutation Index

The index of a PERMUTATION p is defined as the sum of all subscripts j such that $p_j > p_{j+1}$, for $1 \le j \le n$. MacMahon (1960) proved that the number of permutations of size n having index k is the same as the number having exactly k inversions (Skiena 1990,

p. 29). The permutation index can be computed as `Index[p]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Permutation Inversion

A pair of elements (p_i, p_j) is called an inversion in a permutation p if $i > j$ and $p_i < p_j$. For example, in the permutation $a_6a_5a_7a_3a_8$ contains the four inversions a_7a_3, a_5a_3, a_6a_3, and a_6a_5. Inversions are pairs which are out of order, and are important in sorting algorithms (Skiena 1990, p. 27).

The total number of inversions can be obtained by summing the elements of the INVERSION VECTOR, and is implemented as `Inversions[p]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`). The number of inversions in any PERMUTATION is the same as the number of interchanges of consecutive elements *necessary* to arrange them in their natural order (Muir 1960, p. 1). The value $(-1)^{i(p)}$ can be found in *Mathematica* using `Signature[p]`.

The number of inversions in a PERMUTATION is equal to that of its inverse permutation (Skiena 1990, p. 29; Knuth 1998). If, from any permutation, another is formed by interchanging two elements, then the difference between the number of inversions in the two is always an ODD NUMBER.

Permutation Matrix

A MATRIX p_{ij} obtained by permuting the ith and jth rows of the IDENTITY MATRIX with $i < j$. Every row and column therefore contain precisely a single 1, and every permutation corresponds to a unique permutation matrix. A permutation matrix is nonsingular, so the DETERMINANT is always NONZERO.

In addition, a permutation matrix satisfies

$$\mathsf{p}_{ij}^2 = \mathsf{I},$$

where I is the IDENTITY MATRIX. Applying to another MATRIX, $\mathsf{p}_{ij}\mathsf{A}$ gives A with the ith and jth rows interchanged, and $\mathsf{A}\mathsf{p}_{ij}$ gives A with the ith and jth columns interchanged.

Interpreting the 1s in an $n \times n$ permutation matrix as ROOKS gives an allowable configuration of nonattacking ROOKS on an $n \times n$ CHESSBOARD.

See also ALTERNATING SIGN MATRIX, ELEMENTARY MATRIX, IDENTITY, PERMUTATION, ROOK NUMBER

Permutation Pattern

Let $F(n, \sigma)$ denote the number of permutations on the SYMMETRIC GROUP S_n which avoid $\sigma \in S_n$ as a subpattern, where "τ contains σ as a subpattern" is interpreted to mean that there exist $1 \leq x_1 \leq x_2 \leq \ldots \leq x_k \leq n$ such that for $1 \leq i, j \leq k$,

$$\tau(x_i) < \tau(x_j) \tag{1}$$

IFF $\sigma(i) < \sigma(j)$.

For example, a permutation contains the pattern (123) IFF it has an ascending subsequence of length three. Here, note that *members need not actually be consecutive,* merely ascending (Wilf 1997). Therefore, of the $3! = 6$ partitions of $\{1, 2, 3\}$, all but $\{3, 2, 1\}$ (i.e., $\{1, 2, 3\}$, $\{1, 3, 2\}$, $\{2, 1, 3\}$, $\{2, 3, 1\}$, and $\{3, 1, 2\}$) contain the pattern (12) (i.e., an increasing subsequence of length two).

The following table gives the numbers of pattern-matching permutations of k, $k+1$, ..., n numbers for various patterns $(a_1 \ldots a_k)$ of length k.

pattern	Sloane	number of pattern-matching permutations
1	A000142	1, 2, 6, 24, 120, 720, 5040, ...
12	A033312	1, 5, 23, 119, 719, 5039, 40319, ...
α_3	A056986	1, 10, 78, 588, 4611, 38890, ...
1234	A000000	1, 17, 207, ...
1342	A000000	1, 17, 208, ...

The following table gives the numbers of pattern-avoiding permutations of $\{1, \ldots, n\}$ for various sets of patterns.

Wilf class	Sloane	number of pattern-avoiding permutations
α_3	A000108	1, 2, 5, 14, 42, 132, ...
123, 132, 213	A000027	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
132, 231, 321	A000027	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
123, 132, 3214	A000073	1, 2, 4, 7, 13, 24, 44, 81, 149, ...
123, 132, 3241	A000071	1, 2, 7, 12, 20, 33, 54, 88, 143, ...
123, 132, 3412	A000124	1, 2, 4, 7, 11, 16, 22, 29, 37, 46, ...
123, 231, $\alpha_4^{(1)}$	A004275	1, 2, 4, 6, 8, 10, 12, 14, 16, 18, ...
123, 231, $\alpha_4^{(2)}$	A000124	1, 2, 4, 7, 11, 16, 22, 29, 37, 46, ...
123, 231, 4321		1, 2, 4, 6, 3, 1, 0, ...
132, 213, 1234	A000073	1, 2, 4, 7, 13, 24, 44, 81, 149, ...
213, 231, $\alpha_4^{(3)}$	A000124	1, 2, 4, 7, 11, 16, 22, 29, 37, 46, ...

Abbreviations used in the above table are summarized below.

abbreviation	patterns in class
α_3	123, 132, 213, 232, 312, 321
$\alpha_4^{(1)}$	1432, 2143, 3214, 4132, 4213, 4312
$\alpha_4^{(2)}$	1234, 1243, 1324, 1342, 1423, 2134, 2314, 2341, 2413, 2431, 3124,
	3142, 3241, 3412, 3421, 4123, 4231
$\alpha_4^{(3)}$	1234, 1243, 1423, 1432

Permutation Pseudotensor

Permutation Tensor

Permutation Run

A set of ascending sequences in a permutation is called a run. A sorted permutation consists of a single run, whereas a reverse permutation consists of n runs, each of length 1. Runs are closely related to permutation ascents, with n runs implying $n-1$ ascents (Skiena 1990, p. 31). The number of runs in a permutation can be computed using `Runs[p]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``). The number of permutations of length n with exactly k runs is given by the Eulerian number $\left\langle {n \atop k} \right\rangle$.

Surprisingly, the expected length of the first run is shorter than the expected length of the second run (Gassner 1967; Skiena 1990, p. 30; Knuth 1998).

Permutation Symbol

A three-index object sometimes called the Levi-Civita symbol or signature, and defined by

$$\epsilon_{ijk} = \begin{cases} 0 & \text{for } i=j,\ j=k, \text{ or } k=i \\ +1 & \text{for } (i, j, k) \in \{(1, 2, 3), (2, 3, 1), (3, 1, 2)\} \\ -1 & \text{for } (i, j, k) \in \{(1, 3, 2), (3, 2, 1), (2, 1, 3)\}. \end{cases} \tag{1}$$

The permutation symbol is implemented in *Mathematica* as `Signature[`*list*`]`. The permutation symbol satisfies

$$\delta_{ij}\epsilon_{ijk} = 0 \tag{2}$$

$$\epsilon_{ipq}\epsilon_{jpq} = 2\delta_{ij} \tag{3}$$

$$\epsilon_{ijk}\epsilon_{ijk} = 6 \tag{4}$$

$$\epsilon_{ijk}\epsilon_{pqk} = \delta_{ip}\delta_{jq} - \delta_{iq}\delta_{jp}, \tag{5}$$

where δ_{ij} is the KRONECKER DELTA. The symbol can be defined as the SCALAR TRIPLE PRODUCT of unit vectors in a right-handed coordinate system,

$$\epsilon_{ijk} \equiv \hat{\mathbf{x}}_i \cdot (\hat{\mathbf{x}}_j \times \hat{\mathbf{x}}_k). \tag{6}$$

The symbol can also be interpreted as a TENSOR, in which case it is called the PERMUTATION TENSOR.

The symbol can be generalized to an arbitrary number of elements, in which case the permutation symbol is $(-1)^{i(p)}$, where $i(p)$ is the number of transpositions of pairs of elements (i.e., PERMUTATION INVERSIONS) that must be composed to build up the permutation p (Skiena 1990). This type of symbol arises in computation of determinants of $n \times n$ matrices. The number of permutations on n symbols having signature -1 is $n!/2$, which is also the number of permutations having signature $+1$.

Permutation Tensor

A PSEUDOTENSOR which is ANTISYMMETRIC under the interchange of any two slots. Recalling the definition of the PERMUTATION SYMBOL in terms of a SCALAR TRIPLE PRODUCT of the Cartesian unit vectors,

$$\epsilon_{ijk} \equiv \hat{\mathbf{x}}_i \cdot (\hat{\mathbf{x}}_j \times \hat{\mathbf{x}}_k) = [\hat{\mathbf{x}}_i,\ \hat{\mathbf{x}}_j,\ \hat{\mathbf{x}}_k], \tag{1}$$

the pseudotensor is a generalization to an arbitrary BASIS defined by

$$\epsilon_{\alpha\beta\cdots\mu} = \sqrt{|g|}[\alpha,\ \beta,\ \ldots,\ \mu] \tag{2}$$

$$\epsilon^{\alpha\beta\cdots\mu} = \frac{[\alpha,\ \beta,\ \ldots,\ \mu]}{\sqrt{|g|}}, \tag{3}$$

where

$$[\alpha,\ \beta,\ \ldots,\ \mu] = \begin{cases} 1 & \text{the arguments are an even permutation} \\ -1 & \text{the arguments are an odd permutation} \\ 0 & \text{two or more arguments are equal,} \end{cases} \tag{4}$$

and $g \equiv \det(g_{\alpha\beta})$, where $g_{\alpha\beta}$ is the METRIC TENSOR. $\epsilon(\mathbf{x}_1, \ldots, \mathbf{x}_n)$ is NONZERO IFF the VECTORS are LINEARLY INDEPENDENT.

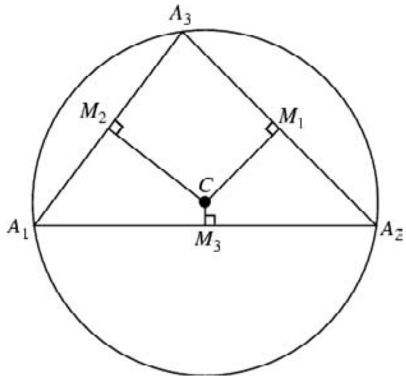
Perpendicular

Two lines, vectors, planes, etc., are said to be perpendicular if they meet at a RIGHT ANGLE. In $\mathbb{R}^n$, two VECTORS $\mathbf{A}$ and $\mathbf{B}$ are PERPENDICULAR if their DOT

PRODUCT

$$\mathbf{A} \cdot \mathbf{B} = 0.$$

In $\mathbb{R}^2$, a LINE with SLOPE $m_2 = -1/m_1$ is PERPENDICULAR to a LINE with SLOPE m_1. Perpendicular objects are sometimes said to be "orthogonal."



In the above figure, the LINE SEGMENT AB is perpendicular to the LINE SEGMENT CD. This relationship is commonly denoted with a small SQUARE at the vertex where perpendicular objects meet, as shown above, and is denoted $AB \perp CD$.

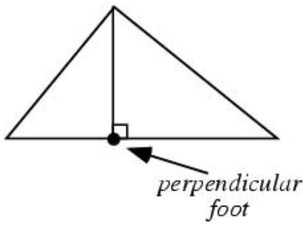
Perpendicular Bisector

The perpendicular bisectors of a TRIANGLE $\Delta A_1A_2A_3$ are lines passing through the MIDPOINT M_i of each side which are PERPENDICULAR to the given side. A TRIANGLE'S three perpendicular bisectors meet (Casey 1888, p. 9) at a point C known as the CIRCUMCENTER (Durell 1928), which is also the center of the TRIANGLE'S CIRCUMCIRCLE.



See also CIRCUMCENTER, MIDPOINT, PERPENDICULAR, PERPENDICULAR FOOT

Perpendicular Foot

The FOOT of the PERPENDICULAR is the point on the leg opposite a given vertex of a TRIANGLE at which the PERPENDICULAR passing through that vertex intersects the side. The length of the LINE SEGMENT from the vertex to the perpendicular foot is called the ALTITUDE of the TRIANGLE.

When a line is drawn from a POINT to a PLANE, its intersection with the PLANE is known as the foot.

Perrin Pseudoprime

If p is PRIME, then $p|P(p)$, where $P(p)$ is a member of the PERRIN SEQUENCE 3, 0, 2, 3, 2, 5, 5, 7, 10, 12, 17, ... (Sloane's A001608). A Perrin pseudoprime is a COMPOSITE NUMBER n such that $n|P(n)$. Several "unrestricted" Perrin pseudoprimes are known, the smallest of which are 271441, 904631, 16532714, 24658561, ... (Sloane's A013998).

Adams and Shanks (1982) discovered the smallest unrestricted Perrin pseudoprime after unsuccessful searches by Perrin (1899), Malo (1900), Escot (1901), and Jarden (1966). (A 1996 article by Stewart's stating that no Perrin pseudoprimes were then known was incorrect.)

Grantham (1996) generalized the definition of Perrin pseudoprime with parameters (r, s) to be an ODD COMPOSITE NUMBER n for which either

1. $(\Delta/n) = 1$ and n has an S-SIGNATURE, or
2. $(\Delta/n) = -1$ and n has a Q-SIGNATURE,

where (a/b) is the JACOBI SYMBOL. All the 55 Perrin pseudoprimes less than 50×10^9 have been computed by Kurtz *et al.* (1986). All have S-SIGNATURE, and form the sequence Sloane calls "restricted" Perrin pseudoprimes: 27664033, 46672291, 102690901, ... (Sloane's A018187).

Perrin Sequence

The INTEGER SEQUENCE defined by the recurrence

$$P(n) = P(n-2) + P(n-3) \tag{1}$$

with the initial conditions $P(0) = 3$, $P(1) = 0$, $P(2) = 2$. This RECURRENCE RELATION is the same as that for the PADOVAN SEQUENCE but with different initial conditions. The first few terms for $n = 0, 1, ...,$ are 3, 0, 2, 3, 2, 5, 5, 7, 10, 12, 17, ... (Sloane's A001608). $P(n)$ is the solution of a third-order linear homogeneous DIFFERENCE EQUATION having characteristic equation

$$x^3 - x - 1 = 0, \tag{2}$$

discriminant -23, and ROOTS

$$\alpha \approx 1.324717957 \tag{3}$$

$$\beta \approx -0.6623589786 + 0.5622795121i \tag{4}$$

$$\gamma \approx -0.6623589786 - 0.5622795121i. \tag{5}$$

The solution is then

$$P(n) = \alpha^n + \beta^n + \gamma^n, \tag{6}$$

where

$$P(n) \sim \alpha^n. \tag{7}$$

Perrin (1899) investigated the sequence and noticed that if n is PRIME, then $n|P(n)$. The first statement of this fact is attributed to É. Lucas in 1876 by Stewart (1996). Perrin also searched for but did not find any COMPOSITE NUMBER n in the sequence such that $n|P(n)$. Such numbers are now known as PERRIN PSEUDOPRIMES. Malo (1900), Escot (1901), and Jarden (1966) subsequently investigated the series and also found no PERRIN PSEUDOPRIMES. Adams and Shanks (1982) subsequently found that 271,441 is such a number.

Perron-Frobenius Operator

An OPERATOR which describes the time evolution of densities in PHASE SPACE. The OPERATOR can be defined by

$$\rho_{n+1} = \tilde{L}\rho_n,$$

where ρ_n are the NATURAL DENSITIES after the nth iteration of a map f. This can be explicitly written as

$$\tilde{L}\rho(y) = \sum_{x \in f^{-1}(y)} \frac{\rho(x)}{|f'(x)|}.$$

Perron-Frobenius Theorem

If all elements a_{ij} of an IRREDUCIBLE MATRIX A are NONNEGATIVE, then $R = \min M_\lambda$ is an EIGENVALUE of A and all the EIGENVALUES of A lie on the DISK

$$|z| \le R,$$

where, if $\lambda = (\lambda_1, \ldots, \lambda_2, \ldots, \lambda_n)$ is a set of NONNEGATIVE numbers (which are not all zero),

$$M_\lambda = \inf\left\{\mu : \mu\lambda_i > \sum_{j=1}^n |a_{ij}|\lambda_j,\ 1 \le i \le n\right\}$$

and $R = \min M_\lambda$. Furthermore, if A has exactly p EIGENVALUES ($p \le n$) on the CIRCLE $|z| = R$, then the set of all its EIGENVALUES is invariant under rotations by $2\pi/p$ about the ORIGIN.

Persistence

ADDITIVE PERSISTENCE, MULTIPLICATIVE PERSISTENCE, PERSISTENT NUMBER, PERSISTENT PROCESS

Persistent Number

An n-persistent number is a POSITIVE INTEGER k which contains the digits 0, 1, ..., 9 (i.e., is a PANDIGITAL NUMBER), and for which $2k$, ..., nk also share this property. No ∞-persistent numbers exist. However, the number $k = 1234567890$ is 2-persistent, since $2k = 2469135780$ but $3k = 3703703670$, and the number $k = 526315789473684210$ is 18-persistent. There exists at least one k-persistent number for each POSITIVE INTEGER k.

n	Sloane	n-persistent
1	A051264	1023456798, 1023456897, 1023456978, 1023456987, ...
2	A051018	1023456789, 1023456879, 1023457689, 1023457869, ...
3	A051019	1052674893, 1052687493, 1052746893, 1052748693, ...
4	A051020	1053274689, 1089467253, 1253094867, 1267085493, ...

Persistent Process

A FRACTAL PROCESS for which $H > 1/2$, so $r > 0$.

See also ANTIPERSISTENT PROCESS, FRACTAL PROCESS

Perspective

Perspective is the art and mathematics of realistically depicting 3-D objects in a 2-D plane, sometimes called CENTRIC or NATURAL PERSPECTIVE to distinguish it from BICENTRIC PERSPECTIVE. The study of the projection of objects in a plane is called PROJECTIVE GEOMETRY. The principles of perspective drawing were elucidated by the Florentine architect F. Brunelleschi (1377–1446). These rules are summarized by Dixon (1991):

1. The horizon appears as a line.
2. Straight lines in space appear as straight lines in the image.
3. Sets of PARALLEL lines meet at a VANISHING POINT.
4. Lines PARALLEL to the picture plane appear PARALLEL and therefore have no VANISHING POINT.

There is a graphical method for selecting vanishing points so that a CUBE or box appears to have the correct dimensions (Dixon 1991).

See also BICENTRIC PERSPECTIVE, LEONARDO'S PARADOX, PERSPECTIVE AXIS, PERSPECTIVE CENTER, PERSPECTIVE COLLINEATION, PERSPECTIVE TRIANGLES, PERSPECTIVITY, PROJECTION, PROJECTIVE GEOMETRY, VANISHING POINT, ZEEMAN'S PARADOX

Perspective Axis

The line joining the three collinear points of intersection of the extensions of corresponding sides in PERSPECTIVE TRIANGLES, sometimes also called the homology axis.

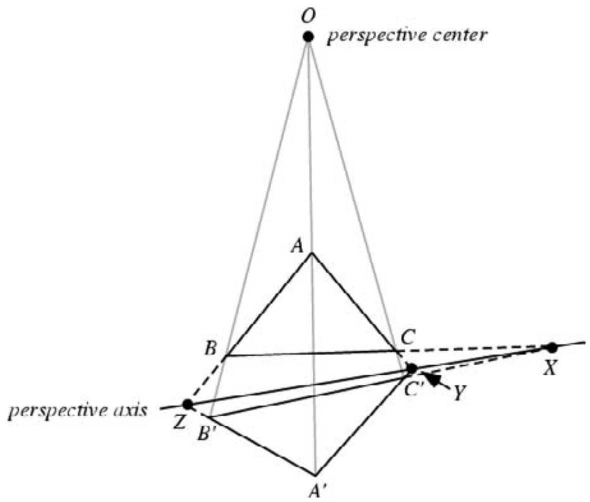
See also PERSPECTIVE CENTER, PERSPECTIVE TRIANGLES, SONDAT'S THEOREM

Perspective Center

The point at which the three LINES connecting the VERTICES of PERSPECTIVE TRIANGLES (from a point) CONCUR, sometimes also called the homology center or pole.

See also PERSPECTIVE AXIS, PERSPECTIVE TRIANGLES

Perspective Collineation



A perspective collineation with center O and axis o is a COLLINEATION which leaves all lines through O and points of o invariant. Every perspective collineation is a PROJECTIVE COLLINEATION.

See also COLLINEATION, ELATION, HOMOLOGY (GEOMETRY), PROJECTIVE COLLINEATION

References

Coxeter, H. S. M. *Introduction to Geometry, 2nd ed.* New York: Wiley, pp. 247–248, 1969.

Perspective Triangles

Two TRIANGLES ΔABC and $\Delta A'B'C'$ are perspective from a line if the extensions of their three pairs of corresponding sides meet in COLLINEAR points X, Y, and Z. The line joining these points is called the PERSPECTIVE AXIS.

Two TRIANGLES are perspective from a point if their three pairs of corresponding VERTICES are joined by lines which meet in a point of CONCURRENCE O. This point is called the PERSPECTIVE CENTER, or sometimes the homology center or pole.

DESARGUES' THEOREM guarantees that if two TRIANGLES are perspective from a point, they are perspective from a line (called the PERSPECTIVE AXIS). Triangles in perspective are sometimes said to be homologous or copolar.

Peters Polynomial

Polynomials $s_k(x;\ \lambda,\ \mu)$ which are a generalization of the BOOLE POLYNOMIALS, form the SHEFFER SEQUENCE for

$$g(t) = (1 + e^{\lambda t})^{\mu} \quad (1)$$

$$f(t) = e^t - 1 \quad (2)$$

and have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{s_k(x;\ \lambda,\ \mu)}{k!} t^k = [1 + (1+t)^{\lambda}]^{-\mu}(1+t)^x. \quad (3)$$

The first few are

$$s_0(x;\ \lambda,\ \mu) = 2^{-\mu}$$

$$s_1(x;\ \lambda,\ \mu) = 2^{-(\mu+1)}(2x - \lambda\mu)$$

$$s_2(x;\ \lambda,\ \mu) = 2^{-(\mu+2)}[4x(x-1) + (2-4x)\lambda\mu + \mu(\mu-1)\lambda^2].$$

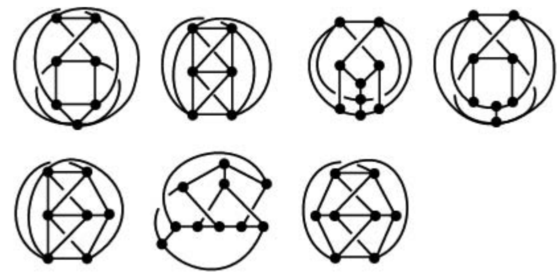
Petersen Graph



"The" Petersen graph is the GRAPH illustrated above possessing ten nodes, all of whose nodes have DEGREE 3 (Saaty and Kainen 1986, Harary 1994, p. 89). The Petersen graph is the only smallest-GIRTH graph which has no Tait coloring, and is the unique 5-CAGE GRAPH (Harary 1994, p. 175). It is the complement of the LINE GRAPH of the COMPLETE GRAPH K_5 (Skiena 1990, p. 139), and the ODD GRAPH O_3 (Skiena 1990, p. 162). It is depicted on the cover of the journal *Discrete Mathematics*. The Petersen graph is the smallest HYPOHAMILTONIAN GRAPH

Petersen graph *embedding on the projective plane*

The Petersen graph provides a 6-color coloring of the PROJECTIVE PLANE.

The seven graphs obtainable from the COMPLETE GRAPH K_6 by repeated triangle-Y exchanges are also called Petersen graphs, where the three EDGES forming the TRIANGLE are replaced by three EDGES and a new VERTEX that form a Y, and the reverse operation is also permitted. A GRAPH is intrinsically linked IFF it contains one of the seven Petersen graphs (Robertson *et al.* 1993).

Petersen-Shoute Theorem

A beautiful general theory of which the following two statements are special cases.

1. If ΔABC and $\Delta A'B'C'$ are two DIRECTLY SIMILAR triangles, while $\Delta AA'A''$, $\Delta BB'B''$, and $\Delta CC'C''$ are three DIRECTLY SIMILAR triangles, then $\Delta A''B''C''$ is directly similar to ΔABC.
2. When all the points P on AB are related by a SIMILARITY TRANSFORMATION to all the points P' on $A'B'$, the points dividing the segment PP' in a given ratio are distant and collinear, or else they coincide.

See also DIRECTLY SIMILAR, SIMILARITY TRANSFORMATION

Peterson-Mainardi-Codazzi Equations

$$\frac{\partial e}{\partial v}-\frac{\partial f}{\partial u}=e\Gamma^1_{12}+f(\Gamma^2_{12}-\Gamma^1_{11})-g\Gamma^2_{11} \tag{1}$$

$$\frac{\partial f}{\partial v}-\frac{\partial g}{\partial u}=e\Gamma^1_{22}+f(\Gamma^2_{22}-\Gamma^1_{12})-g\Gamma^2_{12}, \tag{2}$$

where e, f, and g are coefficients of the second FUNDAMENTAL FORM and Γ^k_{ij} are CHRISTOFFEL SYMBOLS OF THE SECOND KIND. Therefore,

$$\frac{\partial e}{\partial v}=\tfrac{1}{2}E_v\left(\frac{e}{E}+\frac{g}{G}\right) \tag{3}$$

$$\frac{\partial g}{\partial u}=\tfrac{1}{2}G_u\left(\frac{e}{E}+\frac{g}{G}\right) \tag{4}$$

$$\frac{\partial(\ln f)}{\partial u}=\Gamma^1_{11}-\Gamma^2_{12} \tag{5}$$

$$\frac{\partial(\ln f)}{\partial v}=\Gamma^2_{22}-\Gamma^1_{12} \tag{6}$$

$$\frac{\partial}{\partial u}\left(\frac{\ln f}{\sqrt{EG-F^2}}\right)=-2\Gamma^2_{12} \tag{7}$$

$$\frac{\partial}{\partial v}\left(\frac{\ln f}{\sqrt{EG-F^2}}\right)=-2\Gamma^1_{12}, \tag{8}$$

where E, F, and G are coefficients of the first FUNDAMENTAL FORM.

Petersson Conjecture

Petersson considered the absolutely converging DIRICHLET L-SERIES

$$\phi(s)=\prod_p \frac{1}{1-c(p)p^{-s}+p^{2k-1}p^{-2s}}.$$

Writing the DENOMINATOR as

$$1-c(p)x+p^{2k-1}x^2=(1-r_1x)(1-r_2x),$$

where

$$r_1+r_2=c(p)$$

and

$$r_1r_2=p^{2k-1},$$

Petersson conjectured that r_1 and r_2 are always COMPLEX CONJUGATE, which implies

$$|r_1|=|r_2|=p^{k-1/2}$$

and

$$|c(p)|\le 2p^{k-1/2}.$$

This conjecture was proven by Deligne (1974), which also proved the TAU CONJECTURE as a special case. Deligne was awarded the FIELDS MEDAL for his proof.

Petrie Polygon

A SKEW POLYGON such that every two consecutive sides (but no three) belong to a face of a regular POLYHEDRON. Every REGULAR POLYHEDRON can be orthogonally projected onto a plane in such a way that one Petrie polygon becomes a REGULAR POLYGON with the remainder of the projection interior to it. The Petrie polygon of the POLYHEDRON $\{p, q\}$ has h sides, where

$$\cos^2\left(\frac{\pi}{h}\right) = \cos^2\left(\frac{\pi}{p}\right) + \cos^2\left(\frac{\pi}{q}\right).$$

The Petrie polygons shown above correspond to the PLATONIC SOLIDS.

Pfaffian Form

A 1-FORM

$$\omega = \sum_{i=1}^{n} a_i(x)\ dx_i$$

such that

$$\omega = 0.$$

References

Knuth, D. E. "Overlapping Pfaffians." *Electronic J. Combinatorics* **3**, No. 2, R5, 1–13, 1996. http://www.combinatorics.org/Volume_3/volume3_2.html#R5.

p-Form

DIFFERENTIAL k-FORM

p-Good Path

A LATTICE PATH from one point to another is p-good if it lies completely below the line

$$y = (p-1)x.$$

Hilton and Pederson (1991) show that the number of p-good paths from $(1,\ q-1)$ to $(k,\ n-k)$ under the condition $2 \le k \le n-p+1 \le p(k-1)$ is

$$\binom{n-q}{k-1} - \sum_{j=1}^{\ell} {}_p d_{qj} \binom{n-pj}{k-j},$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT, and

$$\ell \equiv \left\lfloor \frac{n-k}{p-1} \right\rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

References

Hilton, P. and Pederson, J. "Catalan Numbers, Their Generalization, and Their Uses." *Math. Intel.* **13**, 64–75, 1991.

p-Group

When p is a PRIME NUMBER, then a p-group is a GROUP, all of whose elements have order some power of p. For a FINITE GROUP, the equivalent definition is that the number of elements in G is a power of p. In fact, every FINITE GROUP has subgroups which are p-groups by the SYLOW THEOREMS, in which case they are called SYLOW P-SUBGROUPS.

Sylow proved that every GROUP of this form has a power-commutator representation on n generators defined by

$$a_i^p = \prod_{k=i+1}^{n} a_k^{\beta(i,\ k)} \tag{1}$$

for $0 \leq \beta(i,\ k) < p$, $1 \leq i \leq n$ and

$$[a_j,\ a_i] = \prod_{k=j+1}^{n} a_k^{\beta(i,\ j,\ k)} \tag{2}$$

for $0 \leq \beta(i,\ j,\ k) < p$, $1 \leq i < j \leq n$. If (p^m) is a PRIME POWER and $f(p^m)$ is the number of GROUPS of order (p^m), then

$$f(p^m) = p^{Am^3}, \tag{3}$$

where

$$\lim_{m\to\infty} A = \tfrac{2}{27} \tag{4}$$

(Higman 1960ab).

Phase

The angular position of a quantity. For example, the phase of a function $\cos(\omega t + \phi_0)$ as a function of time is

$$\phi(t) = \omega t + \phi_0.$$

The ARGUMENT of a COMPLEX NUMBER is sometimes also called the phase.

See also ARGUMENT (COMPLEX NUMBER), COMPLEX NUMBER, PHASOR, RETARDANCE

Phase Space

For a function or object with n DEGREES OF FREEDOM, the n-D SPACE which is accessible to the function or object is called its phase space.

See also WORLD LINE

Phase Transition

Erdos and Rényi (1960) showed that for many monotone-increasing properties of RANDOM GRAPHS, graphs of a size slightly less than a certain threshold are very unlikely to have the property, whereas graphs with a few more EDGES are almost certain to have it. This is known as a PHASE TRANSITION (Janson *et al.* 2000, p. 103).

See also RANDOM GRAPH

References

Erdos, P. and Rényi, A. "On the Evolution of Random Graphs." *Publ. Math. Inst. Hungar. Acad. Sci.* **5**, 17–61, 1960.

Phasor

The representation, beloved of engineers and physicists, of a COMPLEX NUMBER in terms of a COMPLEX exponential

$$x + iy = |z| e^{i\phi}, \tag{1}$$

where I (called J by engineers) is the IMAGINARY NUMBER and the MODULUS and ARGUMENT (also called PHASE) are

$$|z| = \sqrt{x^2 + y^2} \tag{2}$$

$$\phi = \tan^{-1}\left(\frac{y}{x}\right). \tag{3}$$

Here, ϕ (sometimes also denoted θ) is called the ARGUMENT or the PHASE. It corresponds to the counterclockwise ANGLE from the POSITIVE REAL AXIS, i.e., the value of ϕ such that $x = \cos\phi$ and $y = \sin\phi$. The special kind of INVERSE TANGENT used here takes into account the quadrant in which z lies and is returned by the FORTRAN command ATAN2(X,Y) and the *Mathematica* command ArcTan[x, y], and is often restricted to the range $-\pi < \theta \leq \pi$. In the degenerate case when $x = 0$,

$$\phi = \begin{cases} -\frac{1}{2}\pi & \text{if } y < 0 \\ \text{undefined} & \text{if } y = 0 \\ \frac{1}{2}\pi & \text{if } y > 0 \end{cases} \tag{4}$$

It is trivially true that

$$\sum_i \Re[\psi_i] = \Re\left[\sum_i \psi_i\right]. \quad (5)$$

Now consider a SCALAR FUNCTION $\psi \equiv \psi_0 e^{i\phi}$. Then

$$I \equiv [\Re(\psi)]^2 = \left[\tfrac{1}{2}(\psi + \bar{\psi})\right]^2 = \tfrac{1}{4}(\psi + \bar{\psi})^2$$

$$= \tfrac{1}{4}(\psi^2 + 2\psi\bar{\psi} + \bar{\psi}^2), \quad (6)$$

where $\bar{\psi}$ is the COMPLEX CONJUGATE. Look at the time averages of each term,

$$\langle \psi^2 \rangle = \langle \psi_0^2 e^{2i\phi} \rangle = \psi_0^2 \langle e^{2i\phi} \rangle = 0 \quad (7)$$

$$\langle \psi\bar{\psi} \rangle = \langle \psi_0^2 e^{i\phi} \psi_0 e^{-i\phi} \rangle = \psi_0^2 = |\psi|^2 \quad (8)$$

$$\langle \bar{\psi}^2 \rangle = \langle \psi_0^2 e^{-2i\phi} \rangle = \psi_0^2 \langle e^{-2i\phi} \rangle = 0. \quad (9)$$

Therefore,

$$\langle I \rangle = \tfrac{1}{2}|\psi|^2. \quad (10)$$

Consider now two scalar functions

$$\psi_1 \equiv \psi_{1,\,0} e^{i(kr_1 + \phi_1)} \quad (11)$$

$$\psi_2 \equiv \psi_{2,\,0} e^{i(kr_2 + \phi_2)}. \quad (12)$$

Then

$$I \equiv [\Re(\psi_1) + \Re(\psi_2)]^2 = \tfrac{1}{4}[(\psi_1 + \bar{\psi}_1) + (\psi_2 + \bar{\psi}_2)]^2$$

$$= \tfrac{1}{4}[(\psi_1 + \bar{\psi}_1)^2 + (\psi_2 + \bar{\psi}_2)^2$$

$$+ 2(\psi_1\psi_2 + \psi_1\bar{\psi}_2 + \bar{\psi}_1\psi_2 + \bar{\psi}_1\bar{\psi}_2)] \quad (13)$$

$$\langle I \rangle = \tfrac{1}{4}[2\psi_1\bar{\psi}_1 + 2\psi_2\bar{\psi}_2 + 2\psi_1\bar{\psi}_2 + 2\bar{\psi}_1\psi_2]$$

$$= \tfrac{1}{2}[\psi_1(\bar{\psi}_1 + \bar{\psi}_2) + \psi_2(\bar{\psi}_1 + \bar{\psi}_2)]$$

$$= \tfrac{1}{2}(\psi_1 + \psi_2)(\bar{\psi}_1 + \bar{\psi}_2) = \tfrac{1}{2}|\psi_1 + \psi_2|^2. \quad (14)$$

In general,

$$\langle I \rangle = \frac{1}{2}\left|\sum_{i=1}^{n} \psi_i\right|^2. \quad (15)$$

Phi Number System

For every POSITIVE INTEGER n, there is a corresponding finite sequence of distinct INTEGERS $k_1, ..., k_m$ such that

$$n = \phi^{k_1} + \ldots + \phi^{k_m},$$

where ϕ is the GOLDEN RATIO.

Philo Line

Given two intersecting lines OA and AB forming an angle with vertex at O and a point X inside the angle $\angle AOB$, the Philo line (or Philon line) is the shortest LINE SEGMENT AB touching both lines and passing through X. The line is named for Philo of Byzantium who considered the line while attempting to duplicate the cube. The line can be constructed by finding $OY \perp$

AB such that $AX = BY$ (Wells 1991).

The distances along the angle edges x and h and the lengths along the Philo line l and dl can be computed by solving the simultaneous equations

$$r^2 \sin^2 \phi + x^2 = l^2$$

$$h^2 - l^2 = (r \cos \phi + x)^2 - (l + dl)^2$$

$$(2l + dl)^2 = h^2 \sin^2 \theta + (r \cos \theta + x - h \cos \theta)^2$$

$$(h^2 - l^2) + dl^2 = r^2,$$

where θ is the VERTEX ANGLE and the point X has POLAR COORDINATES (r, ϕ).

Philon Line

PHILO LINE

Phragmén-Lindêlöf Theorem

Let $f(z)$ be an ANALYTIC FUNCTION in an angular domain $W : |\arg z| < \alpha\pi/2$. Suppose there is a constant M such that for each $\epsilon > 0$, each finite boundary point has a NEIGHBORHOOD such that $|f(z)| < M + \epsilon$ on the intersection of D with this NEIGHBORHOOD, and that for some POSITIVE number $\beta > \alpha$ for sufficiently large $|z|$, the INEQUALITY $|f(z)| < \exp(|z|^{1/\beta})$ holds. Then $|f(z)| \le M$ in D.

Phyllotaxis

The beautiful arrangement of leaves in some plants, called phyllotaxis, obeys a number of subtle mathematical relationships. For instance, the florets in the head of a sunflower form two oppositely directed spirals: 55 of them clockwise and 34 counterclockwise. Surprisingly, these numbers are consecutive FIBONACCI NUMBERS. The ratios of alternate FIBONACCI NUMBERS are given by the convergents to ϕ^{-2}, where ϕ is the GOLDEN RATIO, and are said to measure the fraction of a turn between successive leaves on the stalk of a plant: 1/2 for elm and linden, 1/3 for beech and hazel, 2/5 for oak and apple, 3/8 for poplar and rose, 5/13 for willow and almond, etc. (Coxeter 1969, Ball and Coxeter 1987). A similar phenomenon occurs for DAISIES, pineapples, pinecones, cauliflowers, and so on.

Lilies, irises, and the trillium have three petals; columbines, buttercups, larkspur, and wild rose have five petals; delphiniums, bloodroot, and cosmos have eight petals; corn marigolds have 13 petals; asters have 21 petals; and daisies have 34, 55, or 89 petals–all FIBONACCI NUMBERS.

Pi

A REAL NUMBER denoted π which is defined as the ratio of a CIRCLE'S CIRCUMFERENCE C to its DIAMETER $\pi = 2r$,

$$\pi \equiv \frac{C}{d} = \frac{C}{2r} \tag{1}$$

It is equal to

$$\pi = 3.141592653589793238462643383279502884197\ldots \tag{2}$$

(Sloane's A000796). PI'S DIGITS have many interesting properties, although not very much is known about their analytic properties. PI'S CONTINUED FRACTION is given by [3, 7, 15, 1, 292, 1, 1, 1, ...] (Sloane's A001203).

π is known to be IRRATIONAL (Lambert 1761, Legendre 1794, Hermite 1873, Nagell 1951, Niven 1956, Struik 1969, Königsberger 1990, Schröder 1993, Stevens 1999). In 1794, Legendre also proved that π^2 is IRRATIONAL (Wells 1986, p. 76). π is also TRANSCENDENTAL (Lindemann 1882). An immediate consequence of Lindemann's proof of the transcendence of π also proved that the GEOMETRIC PROBLEM OF ANTIQUITY known as CIRCLE SQUARING is impossible. A simplified, but still difficult, version of Lindemann's proof is given by Klein (1955).

It is also known that π is not a LIOUVILLE NUMBER (Mahler 1953). The following table summarizes progress in computing upper bounds on the IRRATIONALITY MEASURE for π. It is likely that the exponent can be reduced to $2+\epsilon$, where ϵ is an infinitesimally small number (Borwein *et al.* 1989).

upper bound	reference
20	Mahler (1953), Le Lionnais (1983, p. 50)
14.65	Chudnovsky and Chudnovsky (1984)
8.0161	Hata (1992)

It is not known if $\pi + e$, π/e, or $\ln \pi$ are IRRATIONAL. However, it is known that they cannot satisfy any POLYNOMIAL equation of degree ≤ 8 with INTEGER COEFFICIENTS of average size 10^9 (Bailey 1988, Borwein *et al.* 1989).

J. H. Conway has shown that there is a sequence of fewer than 40 FRACTIONS F_1, F_2, ... with the property that if you start with 2^n and repeatedly multiply by the first of the F_i that gives an integer result until a POWER of 2 (say, 2^k) occurs, then k is the nth decimal digit of π.

π crops up in all sorts of unexpected places in mathematics besides CIRCLES and SPHERES. For example, it occurs in the normalization of the GAUSSIAN DISTRIBUTION, in the distribution of PRIMES, in the construction of numbers which are very close to INTEGERS (the RAMANUJAN CONSTANT), and in the probability that a pin dropped on a set of PARALLEL lines intersects a line (BUFFON'S NEEDLE PROBLEM). Pi also appears as the average ratio of the actual length and the direct distance between source and mouth in a meandering river (Støllum 1996, Singh 1997).

A brief history of NOTATION for pi is given by Castellanos (1988). π is sometimes known as LUDOLPH'S CONSTANT after Ludolph van Ceulen (1539–1610), a Dutch π calculator. The symbol π was first used by English mathematician William Jones in 1706, and subsequently adopted by Euler. In *Measurement of a Circle,* Archimedes (ca. 225 BC) obtained the first rigorous approximation by INSCRIBING and CIRCUMSCRIBING $6 \cdot 2^n$-gons on a CIRCLE using the ARCHIMEDES ALGORITHM. Using $n = 4$ (a 96-gon), Archimedes obtained

$$3 + \tfrac{10}{71} < \pi < 3 + \tfrac{1}{7} \tag{3}$$

(Wells 1986, p. 49; Shanks 1993, p. 140).

The Bible contains two references (I Kings 7:23 and Chronicles 4:2) which give a value of 3 for π (Wells 1986, p. 48). It should be mentioned, however, that both instances refer to a value obtained from physical measurements and, as such, are probably well within the bounds of experimental uncertainty. I Kings 7:23 states, "Also he made a molten sea of ten cubits from brim to brim, round in compass, and five cubits in height thereof; and a line thirty cubits did compass it round about." This implies $\pi = C/d = 30/10 = 3$. The Babylonians gave an estimate of π as $3 + 1/8 = 3.125$. The Egyptians did better still, obtaining $2^8/3^4 = 3.1605\ldots$ in the Rhind papyrus, and 22/7 elsewhere. The Chinese geometers, however, did best of all, rigorously deriving π to 6 decimal places.

There are many, many FORMULAS FOR PI, from the simple to the very complicated.

Ramanujan (1913–14) and Olds (1963) give geometric constructions for 355/113. Gardner (1966, pp. 92–93) gives a geometric construction for $3+16/113=3.1415929\ldots$. Dixon (1991) gives constructions for $6/5(1+\phi)=3.141640\ldots$ and $\sqrt{4+[3-\tan(30^\circ)]^2}=3.141533\ldots$. Constructions for approximations of π are approximations to CIRCLE SQUARING (which is itself impossible).

Pi Approximations

KOCHANSKY'S APPROXIMATION is the ROOT of

$$9x^4 - 240x^2 + 1492. \tag{1}$$

given by

$$\pi \approx \sqrt{\tfrac{40}{3} - \sqrt{12}} \approx 3.141533. \tag{2}$$

An approximation involving the GOLDEN MEAN is

$$\pi \approx \tfrac{6}{5}\,\phi^2 = \frac{6}{5}\left(\frac{\sqrt{5}+1}{2}\right)^2 = \tfrac{3}{5}\left(3+\sqrt{5}\right) = 3.14164\ldots. \tag{3}$$

Some approximations due to Ramanujan include

$$\pi \approx \frac{19\sqrt{7}}{16} \tag{4}$$

$$\approx \tfrac{7}{3}\left(1+\tfrac{1}{5}\sqrt{3}\right) \tag{5}$$

$$\approx \tfrac{9}{5}+\sqrt{\tfrac{9}{5}} \tag{6}$$

$$\approx \left(\tfrac{2143}{22}\right)^{1/4}$$

$$= \left(9^2+\frac{19^2}{22}\right)^{1/4} \tag{7}$$

$$= \left(102-\frac{2222}{22^{22}}\right)^{1/4} \tag{8}$$

$$= \left(97+\tfrac{1}{2}-\tfrac{1}{11}\right)^{1/4} \tag{9}$$

$$= \left(97+\tfrac{9}{22}\right)^{1/4} \tag{10}$$

$$\approx \frac{63}{25}\left(\frac{17+15\sqrt{5}}{7+15\sqrt{5}}\right) \tag{11}$$

$$\approx \frac{355}{113}\left(1-\frac{0.003}{3533}\right) \tag{12}$$

$$\approx \frac{12}{\sqrt{130}}\ln\left[\frac{(3+\sqrt{13})(\sqrt{8}+\sqrt{10})}{2}\right] \tag{13}$$

$$\approx \frac{24}{\sqrt{142}}\ln\left[\frac{\sqrt{10+11\sqrt{2}}+\sqrt{10+7\sqrt{2}}}{2}\right] \tag{14}$$

$$\approx \frac{12}{\sqrt{190}}\ln\left[\left(3+\sqrt{10}\right)\left(\sqrt{8}+\sqrt{10}\right)\right] \tag{15}$$

$$\approx \frac{12}{\sqrt{310}}\ln\left[\tfrac{1}{4}\left(3+\sqrt{5}\right)\left(2+\sqrt{2}\right) \times\left(5+2\sqrt{10}+\sqrt{61+20\sqrt{10}}\right)\right] \tag{16}$$

$$\approx \frac{4}{\sqrt{522}}\ln\left[\left(\frac{5+\sqrt{29}}{\sqrt{2}}\right)^3\left(5\sqrt{29}+11\sqrt{6}\right) \times\left(\sqrt{\frac{9+3\sqrt{6}}{4}}+\sqrt{\frac{5+3\sqrt{6}}{4}}\right)^6\right], \tag{17}$$

which are accurate to 3, 4, 4, 8, 8, 9, 14, 15, 15, 18, 23, 31 digits, respectively (Ramanujan 1913–1914; Hardy 1952, p. 70; Wells 1986, p. 54; Berndt 1994, pp. 48–49 and 88–89).

S. Irvine noted that (0), giving an approximation to π good to 8 digits, can be written in a form using all digits 0–9,

$$\pi \approx \left(\frac{2143}{22}\right)^{1/4} = 0+\sqrt{\sqrt{3^3+\frac{19^2}{78-56}}} \tag{18}$$

(S. Plouffe). E. Pegg notes that

$$0+3+\frac{1-(9-8^{-5})-6}{7+2^{-4}}$$

$$= \frac{2335469214202557776949708833181535571}{7434029396811578565492745586638859\,3} \tag{19}$$

approximates π to 9 digits.

Castellanos (1988) gives a slew of curious formulas:

$$\pi \approx (2e^3+e^8)^{1/7} \tag{20}$$

$$\approx \left(\frac{553}{311+1}\right)^2 \tag{21}$$

$$\approx \left(\tfrac{3}{14}\right)^4\left(\tfrac{193}{5}\right)^2 \tag{22}$$

$$\approx \left(\tfrac{296}{167}\right)^2 \tag{23}$$

$$\approx \left(\frac{66^3+86^2}{55^3}\right)^2 \tag{24}$$

$$\approx 1.09999901 \cdot 1.19999911 \cdot 1.39999931 \cdot 1.69999961 \tag{25}$$

$$\approx \frac{47^3+20^3}{30^3}-1 \tag{26}$$

$$\approx 2+\sqrt{1+\left(\tfrac{413}{750}\right)^2} \tag{27}$$

$$\approx \left(\tfrac{77729}{254}\right)^{1/5} \tag{28}$$

$$\approx \left(31+\frac{62^2+14}{28^4}\right)^{1/3} \tag{29}$$

$$\approx \frac{1700^3+82^3-10^3-9^3-6^3-3^3}{69^5} \tag{30}$$

$$\approx \left(95+\frac{93^4+34^4+17^4+88}{75^4}\right)^{1/4} \tag{31}$$

$$\approx \left(100-\frac{2125^3+214^3+30^3+37^2}{82^5}\right)^{1/4}, \tag{32}$$

which are accurate to 3, 4, 4, 5, 6, 7, 7, 8, 9, 10, 11, 12, and 13 digits, respectively. An extremely accurate

approximation due to Shanks (1982) is

$$\pi \approx \frac{6}{\sqrt{3502}} \ln(2u) + 7.37 \times 10^{-82}, \tag{33}$$

where u is the product of four simple quartic units. A sequence of approximations due to Plouffe includes

$$\pi \approx 43^{7/23} \tag{34}$$

$$\approx \frac{\ln 2198}{\sqrt{6}} \tag{35}$$

$$\approx \left(\tfrac{13}{4}\right)^{1181/1216} \tag{36}$$

$$\approx \frac{689}{396 \ln\left(\frac{689}{396}\right)} \tag{37}$$

$$\approx \left(\tfrac{2143}{22}\right)^{1/4} \tag{38}$$

$$\approx \sqrt{\frac{9}{67} \ln 5280} \tag{39}$$

$$\approx \left(\tfrac{63023}{30510}\right)^{1/3} + \tfrac{1}{4} + \tfrac{1}{2}\left(\sqrt{5} + 1\right) \tag{40}$$

$$\approx \tfrac{48}{23} \ln\left(\frac{60318}{13387}\right) \tag{41}$$

$$\approx \left(228 + \tfrac{16}{1329}\right)^{1/41} + 2 \tag{42}$$

$$\approx \tfrac{125}{123} \ln\left(\frac{28102}{1277}\right) \tag{43}$$

$$\approx \tfrac{276694819753963^{1/158}}{226588} + 2 \tag{44}$$

$$\approx \frac{\ln 262537412640768744}{\sqrt{163}}, \tag{45}$$

which are accurate to 4, 5, 7, 7, 8, 9, 10, 11, 11, 11, 23, and 30 digits, respectively.

An approximation due to Stoschek using powers of two and the special number 163 (the largest HEEGNER NUMBER) is given by

$$\pi \approx \frac{2^9}{163} = \frac{512}{163} \approx 3.1411043, \tag{46}$$

which is good to 3 digits. A fraction with small numerator and denominator which gives is close approximation to π is

$$\frac{311}{99} = 3.14141414\ldots. \tag{47}$$

Some approximations involving the ninth roots of rational numbers include

$$\pi \approx \left(\frac{4297607660}{144171}\right)^{1/9} \tag{48}$$

$$\pi \approx \left(\frac{4297607660}{144171}\right)^{1/9}, \tag{49}$$

which are good to 12 and 15 digits, respectively (P. Galliani).

J. Iuliano found

$$\pi \approx \left(\frac{19}{60} + \frac{1}{\sqrt{3 \cdot 123449}}\right)^{-1}, \tag{50}$$

which is good to 11 digits. Rivera gives other approximation formulas.

Pi Continued Fraction

The SIMPLE CONTINUED FRACTION for PI, which gives the "best" approximation of a given order, is [3, 7, 15, 1, 292, 1, 1, 1, 2, 1, 3, 1, 14, 2, 1, 1, 2, 2, 2, 2, ...] (Sloane's A001203; Havermann). The very large term 292 means that the CONVERGENT

$$[3,\ 7,\ 15,\ 1] = [3,\ 7,\ 16] = \tfrac{355}{113} = 3.1415929\ldots \tag{1}$$

is an extremely good approximation. The first few CONVERGENTS are 22/7, 333/106, 355/113, 103993/33102, 104348/33215, ... (Sloane's A002485 and A002486). A nice expression for the third convergent of π is given by

$$\pi \approx 2[1,\ 1,\ 1,\ 3,\ 32] = \tfrac{355}{113} \approx 3.14159292\ldots \tag{2}$$

(Stoschek).

Gosper has computed 17,001,303 terms of π's CONTINUED FRACTION (Gosper 1977, Ball and Coxeter 1987), a record which was recently upped to 20,000,000 by H. Havermann in June 1999 (Plouffe). The first occurrences of n in the CONTINUED FRACTION are 4, 9, 1, 30, 40, 32, 2, 44, 130, 100, ... (Sloane's A032523). The smallest integer which does not occur in the first 20,000,000 terms is 2297. The sequence of

increasing terms in the CONTINUED FRACTION is 3, 7, 15, 292, 436, 20776, 78629, 179136, 528210, 12996958, 878783625, ... (Sloane's A033089), occurring at positions 1, 2, 3, 5, 308, 432, 28422, 156382, 267314, 453294, 11504931 ... (Sloane's A033090).

The following table gives the first few occurrences of d-digit terms in the CONTINUED FRACTION of π, counting 3 as the 0th (e.g., Choong *et al.* 1971, Beeler *et al.* 1972).

d	Sloane	Terms/Positions
1	Sloane's A048292	3, 7, 1, 1, 1, 1, 2, 1, 3, 1, 2, 1, 1, 2, ...
	Sloane's A048293	0, 1, 3, 5, 6, 7, 8, 9, 10, 11, 13, 14, ...
2	Sloane's A048294	15, 14, 84, 15, 13, 99, 12, 16, 45, 22, ...
	Sloane's A048955	2, 12, 21, 25, 27, 33, 54, 77, 80, 82, ...
3	Sloane's A048956	292, 161, 120, 127, 436, 106, 141, ...
	Sloane's A048957	4, 79, 196, 222, 307, 601, 669, 725, ...
4	Sloane's A048958	1722, 2159, 8277, 1431, 1282, 2050, ...
	Sloane's A048959	3273, 3777, 3811, 4019, 4700, 6209, ...
5	Sloane's A048960	20776, 19055, 19308, 78629, 17538, ...
	Sloane's A048961	431, 15543, 23398, 28421, 51839, ...
6	Sloane's A048962	179136, 528210, 104293, 196030, ...
	Sloane's A048963	156381, 267313, 294467, 513205, ...
7	Sloane's A048964	8093211, 1811791, 3578547, ...
	Sloane's A048965	1118727, 2782369, 2899883, ...
8	Sloane's A048966	12996958, ...
	Sloane's A048967	453293, ...
9	Sloane's A048968	878783625, ...
	Sloane's A048969	11504930, ...

The SIMPLE CONTINUED FRACTION for π does not show any obvious patterns, but clear patterns *do* emerge in the beautiful non-simple CONTINUED FRACTIONS

$$\frac{4}{\pi}=1+\cfrac{1^2}{2+\cfrac{3^2}{2+\cfrac{5^2}{2+\cfrac{7^2}{2+\ldots}}}} \tag{3}$$

(Brouckner), giving convergents 1, 3/2, 15/13, 105/76, 315/263, ... (Sloane's A025547 and A007509) and

$$\frac{\pi}{2}=1-\cfrac{1}{3-\cfrac{2\cdot 3}{1-\cfrac{1\cdot 2}{3-\cfrac{4\cdot 5}{1-\cfrac{3\cdot 4}{3-\cfrac{6\cdot 7}{1-\cfrac{5\cdot 6}{3-\ldots}}}}}}} \tag{4}$$

(Stern 1833), giving convergents 1, 2/3, 4/3, 16/15, 64/45, 128/105, ... (Sloane's A001901 and A046126).

Pi Digits

The calculation of the π's digits has occupied mathematicians since the day of the Rhind papyrus (1500 BC). Ludolph van Ceulen spent much of his life calculating π to 35 places. Although he did not live to publish his result, it was inscribed on his gravestone. Wells (1986, p. 48) discusses a number of other calculations. The calculation of π also figures in the *Star Trek* episode "Wolf in the Fold," in which Captain Kirk and Mr. Spock force an evil entity (composed of pure energy and which feeds on fear) out of the starship *Enterprise*'s computer by commanding the computer to "compute to the last digit

the value of pi," thus sending the computer into an infinite loop.

π has recently (Sep. 20, 1999) been computed to a world record $206,158,430,208 \approx 3 \cdot 2^{36}$ DECIMAL DIGITS by Y. Kanada (Kanada, Plouffe). This calculation was done using Borwein's fourth-order convergent algorithm and required 46 hours on a massively parallel 1024-processor Hitachi SR8000 supercomputer. The largest number of digits of π computing using a PC is $6,442,450,944 \approx 3 \cdot 21^{31}$ DECIMAL DIGITS by S. Kondo on Jan. 13, 2000 (Gourdon). One billion digits of π are accessible from Plouffe's web site.

Between April 19, 1998, and Feb. 9, 1999, 126 computers from eighteen different countries set a new record for calculating specific bits of π using a program written by C. Percival. The calculation took a total of about 84,500 CPU hours and was done using idle CPU cycles under Windows 95 and Windows NT. The answer, starting at the 39,999,999,999,997th bit of π is

$$1010000011111001111111110011011100011101$$
$$000101110101100100111110000, \qquad (1)$$

so the 40 trillionth bit of π is 0 (Plouffe).

In the following, the word "digit" refers to decimal digit after the decimal point. The following table gives the starting positions for strings of n copies of the digit d.

d	n	Sloane	Positions
0	1	Sloane's A050200	32, 50, 54, 65, 71, 77, 85, 97, ...

The following table gives the first few positions at which a digit d occurs n times. Note that the sequence 9999998 occurs at decimal 762 (which is sometimes called the FEYNMAN POINT; Wells 1986,

p. 51). This is the largest value of any seven digits in the first million decimals.

d	Sloane	strings of 1, 2, ... ds first occur at
0	Sloane's A050279	32, 307, 601, 13390, 17534, 1699927, ...
1	Sloane's A050280	1, 94, 153, 12700, 32788, 255945, ...
2	Sloane's A050281	6, 135, 1735, 4902, 65260, 963024, ...
3	Sloane's A050282	9, 24, 1698, 28467, 28467, 710100, ...
4	Sloane's A050283	2, 59, 2707, 54525, 808650, 828499, ...
5	Sloane's A050284	4, 130, 177, 24466, 24466, 244453, ...
6	Sloane's A050285	7, 117, 2440, 21880, 48439, 252499, ...
7	Sloane's A050286	13, 559, 1589, 1589, 162248, 399579, ...
8	Sloane's A050287	11, 34, 4751, 4751, 213245, 222299, ...
9	Sloane's A050288	5, 44, 762, 762, 762, 762, 1722776, ...

The first time the BEAST NUMBER 666 appears is decimal 2440. The digits 314159 appear at least six times in the first 10 million decimal places of π (Pickover 1995). The sequence 0123456789 occurs beginning at digits 17,387,594,880, 26,852,899,245, 30,243,957,439, 34,549,153,953, 41,952,536,161, and 43,289,964,000 (cf. Wells 1986, p. 51). The sequence 9876543210 occurs beginning at digits 21,981,157,633, 29,832,636,867, 39,232,573,648, 42,140,457,481, and 43,065,796,214. The sequence 27182818284 (the first few digits of *E*) occur beginning at digit 45,111,908,393. There are also interesting patterns for $1/\pi$. 0123456789 occurs at 6,214,876,462, 9876543210 occurs at 15,603,388,145 and 51,507,034,812, and 999999999999 occurs at 12,479,021,132 of $1/\pi$.

Scanning the decimal expansion of π until all n-digit numbers have occurred, the last 1-, 2-, ... digit numbers appearing are 0, 68, 483, 6716, 33394, 569540, ... (Sloane's A032510). These end at digits 32, 606, 8555, 99849, 1369564, 14118312, ... (Sloane's A036903).

The last n-digit number seen in the decimal expansion of π for $n = 1, 2, ...$ are 0, 68, 483, 6716, 33394, 569540, 1075656, ... (Sloane's A032150). The last digits of these numbers occur at positions 32, 606, 8555, 99849, ... (Sloane's A036903).

It is *not* known if π is NORMAL (Wagon 1985, Bailey and Crandall 2000), although the first 30 million DIGITS are very UNIFORMLY DISTRIBUTED (Bailey 1988). The following distribution is found for the first n DIGITS of $\pi - 3$. It shows no statistically SIGNIFICANT departure from a UNIFORM DISTRIBUTION (technically, in the CHI-SQUARED TEST, it has a value of $\chi_s^2 = 5.60$ for the first 5×10^{10} terms).

digit	1×10^5	1×10^6	6×10^9	5×10^{10}
0	9,999	99,959	599,963,005	5,000,012,647
1	10,137	99,758	600,033,260	4,999,986,263
2	9,908	100,026	599,999,169	5,000,020,237
3	10,025	100,229	600,000,243	4,999,914,405
4	9,971	100,230	599,957,439	5,000,023,598
5	10,026	100,359	600,017,176	4,999,991,499
6	10,029	99,548	600,016,588	4,999,928,368
7	10,025	99,800	600,009,044	5,000,014,860
8	9,978	99,985	599,987,038	5,000,117,637
9	9,902	100,106	600,017,038	4,999,990,486

The digits of $1/\pi$ are also very uniformly distributed ($\chi_s^2 = 7.04$), as shown in the following table.

digit	5×10^{10}
0	4,999,969,955
1	5,000,113,699
2	4,999,987,893
3	5,000,040,906
4	4,999,985,863
5	4,999,977,583
6	4,999,990,916
7	4,999,985,552
8	4,999,881,183
9	5,000,066,450

Pi Formulas

A method similar to Archimedes' can be used to estimate π by starting with an n-gon and then relating the AREA of subsequent $2n$-gons. Let β be the ANGLE from the center of one of the POLYGON's segments,

$$\beta = \tfrac{1}{4}(n-3)\pi, \tag{1}$$

then

$$\pi = \frac{2\sin(2\beta)}{(n-3)\prod_{k=0}^{\infty}\cos(2^{-k}\beta)} \tag{2}$$

(Beckmann 1989, pp. 92–94). Viète (1593) was the first to give an exact expression for π by taking $n=4$ in the above expression, giving

$$\cos\beta = \sin\beta = \frac{1}{\sqrt{2}} = \tfrac{1}{2}\sqrt{2}, \tag{3}$$

which leads to an INFINITE PRODUCT of NESTED RADICALS,

$$\frac{2}{\pi} = \sqrt{\tfrac{1}{2}}\sqrt{\tfrac{1}{2}+\tfrac{1}{2}\sqrt{\tfrac{1}{2}}}\sqrt{\tfrac{1}{2}+\tfrac{1}{2}\sqrt{\tfrac{1}{2}+\tfrac{1}{2}\sqrt{\tfrac{1}{2}}}}\cdots \tag{4}$$

(Wells 1986, p. 50; Beckmann 1989, p. 95). However, this expression was not rigorously proved to converge until Rudio (1892). A related formula is given by

$$\pi = \lim_{n\to\infty} 2^n \sqrt{2-\underbrace{\sqrt{2+\sqrt{2+\sqrt{2+\ldots+\sqrt{2}}}}}_{n}}, \tag{5}$$

where the square root term can be written using the iteration

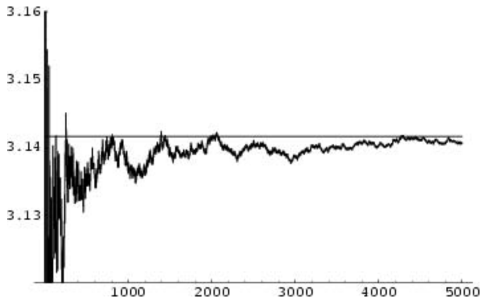
$$\pi_n = \sqrt{\left(\tfrac{1}{2}\pi_{n-1}\right)^2 + \left[1-\sqrt{1-\left(\tfrac{1}{2}\pi_{n-1}\right)^2}\right]^2}, \tag{6}$$

where $\pi_0 = \sqrt{2}$ (J. Munkhammer). The formula

$$\pi = 2\lim_{m\to\infty} \times \sum_{n=1}^{m}\sqrt{\left[\sqrt{1-\left(\frac{n-1}{m}\right)^2}-\sqrt{1-\left(\frac{n}{m}\right)^2}\right]^2+\frac{1}{m^2}} \tag{7}$$

is also closely related.

Another exact FORMULA is MACHIN'S FORMULA, which is



$$\frac{\pi}{4} = 4\tan^{-1}\left(\tfrac{1}{5}\right) - \tan^{-1}\left(\tfrac{1}{239}\right). \tag{8}$$

There are three other MACHIN-LIKE FORMULAS, as well as other FORMULAS with more terms. An interesting INFINITE PRODUCT formula due to Euler which relates π and the nth PRIME p_n is

$$\pi = \frac{2}{\prod_{i=n}^{\infty}\left[1+\frac{\sin\left(\frac{1}{2}\pi p_n\right)}{p_n}\right]} \tag{9}$$

$$= \frac{2}{\prod_{i=n}^{\infty}\left[1+\frac{(-1)^{(p_n-1)/2}}{p_n}\right]} \tag{10}$$

(Blatner 1997, p. 119), plotted below as a function of the number of terms in the product.

The AREA and CIRCUMFERENCE of the UNIT CIRCLE are given by

$$A = \pi = 4\int_0^1 \sqrt{1-x^2}\,dx \tag{11}$$

$$= \lim_{n\to\infty} \frac{4}{n^2}\sum_{k=0}^{n} \sqrt{n^2-k^2} \tag{12}$$

and

$$C = 2\pi = 4\int_0^1 \frac{dx}{\sqrt{1-x^2}} \tag{13}$$

$$= 4\int_0^1 \sqrt{1+\left(\frac{d}{x}\sqrt{1-x^2}\right)^2}\,dx. \tag{14}$$

The SURFACE AREA and VOLUME of the unit SPHERE are

$$S = 4\pi \tag{15}$$

$$V = \tfrac{4}{3}\pi. \tag{16}$$

Beginning with any POSITIVE INTEGER n, round up to the nearest multiple of $n-1$, then up to the nearest multiple of $n-2$, and so on, up to the nearest multiple of 1. Let $f(n)$ denote the result. Then the ratio

$$\lim_{n\to\infty} \frac{n^2}{f(n)} = \pi \tag{17}$$

(Brown). David (1957) credits this result to Jabotinski and Erdos and gives the more precise asymptotic result

$$f(n) = \frac{n^2}{\pi} + \mathcal{O}\left(n^{4/3}\right). \tag{18}$$

The first few numbers in the sequence $\{f(n)\}$ are 1, 2, 4, 6, 10, 12, 18, 22, 30, 34, ... (Sloane's A002491).

A particular case of the WALLIS FORMULA gives

$$\frac{\pi}{2} = \prod_{n=1}^{\infty}\left[\frac{(2n)^2}{(2n-1)(2n+1)}\right]$$

$$= \frac{2\cdot 2}{1\cdot 3}\frac{4\cdot 4}{3\cdot 5}\frac{6\cdot 6}{5\cdot 7}\cdots \tag{19}$$

(Wells 1986, p. 50). This formula can also be written

$$\lim_{n\to\infty}\frac{2^{4n}}{n\binom{2n}{n}^2} = \pi\lim_{n\to\infty}\frac{n[\Gamma(n)]^2}{\left[\Gamma\left(\frac{1}{2}+n\right)\right]^2} = \pi, \tag{20}$$

where $\binom{n}{k}$ denotes a BINOMIAL COEFFICIENT and $\Gamma(x)$ is the GAMMA FUNCTION (Knopp 1990). Euler obtained

$$\pi = \sqrt{6\left(1+\frac{1}{2^2}+\frac{1}{3^2}+\frac{1}{4^2}+\cdots\right)}, \tag{21}$$

which follows from the special value of the RIEMANN ZETA FUNCTION $\zeta(2)=\pi^2/6$. Similar FORMULAS follow from $\zeta(2n)$ for all POSITIVE INTEGERS n. Gregory and Leibniz found

$$\frac{\pi}{4} = 1-\frac{1}{3}+\frac{1}{5}+\cdots \tag{22}$$

(Wells 1986, p. 50), which is sometimes known as GREGORY'S FORMULA or the LEIBNIZ SERIES. The error after the nth term of this series in GREGORY'S FORMULA is larger than $(2n)^{-1}$ so this sum converges so slowly that 300 terms are not sufficient to calculate π correctly to two decimal places! However, it can be transformed to

$$\pi = \sum_{k=1}^{\infty}\frac{3^k-1}{4^k}\,\zeta(k+1), \tag{23}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Vardi 1991, pp. 157–158; Flajolet and Vardi 1996), so that the error after k terms is $\approx (3/4)^k$.

In 1666, Newton used

$$\pi = \tfrac{3}{4}\sqrt{3}+24\int_0^{1/4}\sqrt{x-x^2}\,dx \tag{24}$$

$$= \frac{3\sqrt{3}}{4}+24\left(\frac{1}{12}-\frac{1}{5\cdot 2^5}-\frac{1}{28\cdot 2^7}-\frac{1}{72\cdot 2^9}-\cdots\right) \tag{25}$$

(Wells 1986, p. 50; Borwein *et al.* 1989). The coefficients can be found from the integral

$$I(x) = \int \sqrt{x-x^2}\,dx$$

$$= \tfrac{1}{4}(2x-1)\sqrt{x-x^2}-\tfrac{1}{8}\sin^{-1}(1-2x) \tag{26}$$

by taking the series expansion of $I(x)-I(0)$ about 0, obtaining

$$I(x) = \tfrac{2}{3}x^{3/2}-\tfrac{1}{5}x^{5/2}-\tfrac{1}{28}x^{7/2}-\tfrac{1}{72}x^{9/2}-\tfrac{5}{704}x^{11/2}+\cdots \tag{27}$$

(Sloane's A054387 and A054388). Using Euler's CONVERGENCE IMPROVEMENT transformation gives

$$\frac{\pi}{2} = \frac{1}{2}\sum_{n=0}^{\infty}\frac{(n!)^2 2^{n+1}}{(2n+1)!} = \sum_{n=0}^{\infty}\frac{n!}{(2n+1)!!}$$

$$= 1 + \frac{1}{3} + \frac{1\cdot 2}{3\cdot 5} + \frac{1\cdot 2\cdot 3}{3\cdot 5\cdot 7} + \cdots \quad (28)$$

$$= 1 + \frac{1}{3}\left(1 + \frac{2}{5}\left(1 + \frac{3}{7}\left(1 + \frac{4}{9}(1+\ldots)\right)\right)\right) \quad (29)$$

(Beeler *et al.* 1972, Item 120). This corresponds to plugging $x = 1/\sqrt{2}$ into the POWER SERIES for the HYPERGEOMETRIC FUNCTION ${}_2F_1(a,\ b;\ c;\ x)$,

$$\frac{\sin^{-1} x}{\sqrt{1-x^2}} = \sum_{i=0}^{\infty}\frac{(2x)^{2i+1}(i!)^2}{2(2i+1)!} = {}_2F_1\left(1,\ 1;\ \tfrac{3}{2};\ x^2\right)x. \quad (30)$$

Despite the convergence improvement, series (29) converges at only one bit/term. At the cost of a SQUARE ROOT, Gosper has noted that $x = 1/2$ gives 2 bits/term,

$$\tfrac{1}{9}\sqrt{3}\pi = \frac{1}{2}\sum_{i=0}^{\infty}\frac{(i!)^2}{(2i+1)!}, \quad (31)$$

and $x = \sin(\pi/10)$ gives almost 3.39 bits/term,

$$\frac{\pi}{5\sqrt{\phi+2}} = \frac{1}{2}\sum_{i=0}^{\infty}\frac{(i!)^2}{\phi^{2i+1}(2i+1)!}, \quad (32)$$

where ϕ is the GOLDEN RATIO. Gosper also obtained

$$\pi = 3 + \frac{1}{60}\left(8 + \frac{2\cdot 3}{7\cdot 8\cdot 3}\left(13 + \frac{3\cdot 5}{10\cdot 11\cdot 3}\right.\right.$$
$$\left.\left.\times\left(18 + \frac{4\cdot 7}{13\cdot 14\cdot 3}(23+\ldots)\right)\right)\right). \quad (33)$$

An infinite sum due to Ramanujan is

$$\frac{1}{\pi} = \sum_{n=0}^{\infty}\binom{2n}{n}^3\frac{42n+5}{2^{12n+4}} \quad (34)$$

(Borwein *et al.* 1989). Further sums are given in Ramanujan (1913–14),

$$\frac{4}{\pi} = \sum_{n=0}^{\infty}\frac{(-1)^n(1123+21460n)(2n-1)!!(4n-1)!!}{882^{2n+1}32^n(n!)^3} \quad (35)$$

and

$$\frac{1}{\pi} = \sqrt{8}\sum_{n=0}^{\infty}\frac{(1103+26390n)(2n-1)!!(4n-1)!!}{99^{4n+2}32^n(n!)^3}$$
$$= \frac{\sqrt{8}}{9801}\sum_{n=0}^{\infty}\frac{(4n)!(1103+26390n)}{(n!)^4 396^{4n}} \quad (36)$$

(Beeler *et al.* 1972, Item 139; Borwein *et al.* 1989). Equation (36) is derived from a modular identity of order 58, although a first derivation was not presented prior to Borwein and Borwein (1987). The above series both give

$$\pi \approx \frac{9801}{2206\sqrt{2}} = 3.14159273001\ldots \quad (37)$$

(Wells 1986, p. 54) as the first approximation and provide, respectively, about 6 and 8 decimal places per term. Such series exist because of the rationality of various modular invariants. The general form of the series is

$$\sum_{n=0}^{\infty}[a(t)+nb(t)]\frac{(6n)!}{(3n)!(n!)^3}\frac{1}{[j(t)]^n} = \frac{\sqrt{-j(t)}}{\pi}, \quad (38)$$

where t is a QUADRATIC FORM DISCRIMINANT, $j(t)$ is the J-FUNCTION,

$$b(t) = \sqrt{t[1728 - j(t)]} \quad (39)$$

$$a(t) = \frac{b(t)}{6}\left\{1 - \frac{E_4(t)}{E_6(t)}\left[E_2(t) - \frac{6}{\pi\sqrt{t}}\right]\right\}, \quad (40)$$

and the E_i are RAMANUJAN-EISENSTEIN SERIES. A CLASS NUMBER p field involves pth degree ALGEBRAIC INTEGERS of the constants $A = a(t)$, $B = b(t)$, and $C = c(t)$. The fastest converging series that uses only INTEGER terms corresponds to the largest CLASS NUMBER 1 discriminant of $d = -163$ and was formulated by the Chudnovsky brothers (1987). The 163 appearing here is the same one appearing in the fact that $e^{\pi\sqrt{163}}$ (the RAMANUJAN CONSTANT) is very nearly an INTEGER. The series is given by

$$\frac{1}{\pi} = 12\sum_{n=0}^{\infty}\frac{(-1)^n(6n)!(13591409+545140134n)}{(n!)^3(3n)!(640320^3)^{n+1/2}}$$
$$= \frac{163\cdot 8\cdot 27\cdot 7\cdot 11\cdot 19\cdot 127}{640320^{3/2}}$$
$$\times\sum_{n=0}^{\infty}\left(\frac{13591409}{163\cdot 2\cdot 9\cdot 7\cdot 11\cdot 19\cdot 127} + n\right)$$
$$\times\frac{(6n)!}{(3n)!(n!)^3}\frac{(-1)^n}{640320^{3n}} \quad (41)$$

(Borwein and Borwein 1993). This series gives 14 digits accurately per term. The same equation in another form was given by the Chudnovsky brothers (1987) and is used by *Mathematica* to calculate π (Vardi 1991),

$$\pi = \frac{426880\sqrt{10005}}{A\left[{}_3F_2\left(\tfrac{1}{6},\ \tfrac{1}{2},\ \tfrac{5}{6};\ 1,\ 1;\ B\right) - C\,{}_3F_2\left(\tfrac{7}{6},\ \tfrac{3}{2},\ \tfrac{11}{6};\ 2,\ 2;\ B\right)\right]}, \quad (42)$$

where

$$A \equiv 13591409 \qquad (43)$$

$$B \equiv -\frac{1}{151931373056000} \qquad (44)$$

$$C \equiv \frac{30285563}{1651969144908540723200}. \qquad (45)$$

The best formula for CLASS NUMBER 2 (largest discriminant -427) is

$$\frac{1}{\pi} = 12 \sum_{n=0}^{\infty} \frac{(-1)^n (6n)!(A+Bn)}{(n!)^3 (3n)! C^{n+1/2}}, \qquad (46)$$

where

$$A \equiv 212175710912\sqrt{61} + 1657145277365 \qquad (47)$$

$$B \equiv 13773980892672\sqrt{61} + 107578229802750 \qquad (48)$$

$$C \equiv \left[5280\left(236674 + 30303\sqrt{61}\right)\right]^3 \qquad (49)$$

(Borwein and Borwein 1993). This series adds about 25 digits for each additional term. The fastest converging series for CLASS NUMBER 3 corresponds to $d = -907$ and gives 37–38 digits per term. The fastest converging CLASS NUMBER 4 series corresponds to $d = -1555$ and is

$$\frac{\sqrt{-C^3}}{\pi} = \sum_{n=0}^{\infty} \frac{(6n)!}{(3n)!(n!)^3} \frac{A+nB}{C^{3n}}, \qquad (50)$$

where

$$\begin{aligned} A = {} & 63365028312971999585426220 \\ & +28337702140800842046825600\sqrt{5} \\ & +384\sqrt{5}(10891728551171178200467\ldots \\ & \ldots 436212395209160385656017 \\ & +4879029086578810224\ldots \\ & \ldots 5077338534541688721351255040\sqrt{4})^{1/2} \end{aligned} \qquad (51)$$

$$\begin{aligned} B = {} & 7849910453496627210289749000 \\ & +3510586678260932028965606400\sqrt{5} \\ & +2515968\sqrt{3110}(62602083237890016\ldots \\ & \ldots 36993322654444020882161 \\ & +2799650273060444296\ldots \\ & \ldots 577206890718825190235\sqrt{5})^{1/2} \end{aligned} \qquad (52)$$

$$\begin{aligned} C = {} & -214772995063512240 \\ & -96049403338648032\sqrt{5} \\ & -1296\sqrt{5}(10985234579463550323713318473 \\ & +4912746253692362754607395912\sqrt{5})^{1/2}, \end{aligned} \qquad (53)$$

This gives 50 digits per term. Borwein and Borwein (1993) have developed a general ALGORITHM for generating such series for arbitrary CLASS NUMBER. Bellard gives the exotic formula

$$\pi = \frac{1}{740025}\left[\sum_{n=1}^{\infty} \frac{3P(n)}{\binom{7n}{2n} 2^{n-1}} - 20379280\right], \qquad (54)$$

where

$$\begin{aligned} P(n) \equiv {} & -885673181n^5 + 3125347237n^4 \\ & - 2942969225n^3 + 1031962795n^2 \\ & - 196882274n + 10996648. \end{aligned} \qquad (55)$$

A complete listing of Ramanujan's series for $1/\pi$ found in his second and third notebooks is given by Berndt (1994, pp. 352–354),

$$\frac{4}{\pi} = \sum_{n=0}^{\infty} \frac{(6n+1)\left(\frac{1}{2}\right)_n^3}{4^n (n!)^3} \qquad (56)$$

$$\frac{16}{\pi} = \sum_{n=0}^{\infty} \frac{(42n+5)\left(\frac{1}{2}\right)_n^3}{(64)^n (n!)^3} \qquad (57)$$

$$\frac{32}{\pi} = \sum_{n=0}^{\infty} \frac{(42\sqrt{5}n + 5\sqrt{5} + 30n - 1)\left(\frac{1}{2}\right)_n^3}{(64)^n (n!)^3} \times \left(\frac{\sqrt{5}-1}{2}\right)^{8n} \qquad (58)$$

$$\frac{27}{4\pi} = \sum_{n=0}^{\infty} \frac{(15n+2)\left(\frac{1}{2}\right)_n \left(\frac{1}{3}\right)_n \left(\frac{2}{3}\right)_n}{(n!)^3} \left(\frac{2}{27}\right)^n \qquad (59)$$

$$\frac{15\sqrt{3}}{2\pi} = \sum_{n=0}^{\infty} \frac{(33n+4)\left(\frac{1}{2}\right)_n \left(\frac{1}{3}\right)_n \left(\frac{2}{3}\right)_n}{(n!)^3} \left(\frac{4}{125}\right)^n \qquad (60)$$

$$\frac{5\sqrt{5}}{2\pi\sqrt{3}} = \sum_{n=0}^{\infty} \frac{(11n+1)\left(\frac{1}{2}\right)_n \left(\frac{1}{6}\right)_n \left(\frac{5}{6}\right)_n}{(n!)^3} \left(\frac{4}{125}\right)^n \qquad (61)$$

$$\frac{85\sqrt{85}}{18\pi\sqrt{3}} = \sum_{n=0}^{\infty} \frac{(133n+8)\left(\frac{1}{2}\right)_n \left(\frac{1}{6}\right)_n \left(\frac{5}{6}\right)_n}{(n!)^3} \left(\frac{4}{85}\right)^n \qquad (62)$$

$$\frac{4}{\pi} = \sum_{n=0}^{\infty} \frac{(-1)^n (20n+3)\left(\frac{1}{2}\right)_n \left(\frac{1}{4}\right)_n \left(\frac{3}{4}\right)_n}{(n!)^3 2^{2n+1}} \qquad (63)$$

$$\frac{4}{\pi\sqrt{3}} = \sum_{n=0}^{\infty} \frac{(-1)^n (28n+3)\left(\frac{1}{2}\right)_n \left(\frac{1}{4}\right)_n \left(\frac{3}{4}\right)_n}{(n!)^3 3^n 4^{n+1}} \qquad (64)$$

$$\frac{4}{\pi}=\sum_{n=0}^{\infty}\frac{(-1)^n(260n+23)\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3(18)^{2n+1}} \qquad (65)$$

$$\frac{4}{\pi\sqrt{5}}=\sum_{n=0}^{\infty}\frac{(-1)^n(644n+41)\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3 5^n(72)^{2n+1}} \qquad (66)$$

$$\frac{4}{\pi}=\sum_{n=0}^{\infty}\frac{(-1)^n(21460n+1123)\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3(882)^{2n+1}} \qquad (67)$$

$$\frac{2\sqrt{3}}{\pi}=\sum_{n=0}^{\infty}\frac{(8n+1)^n\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3 9^n} \qquad (68)$$

$$\frac{1}{2\pi\sqrt{2}}=\sum_{n=0}^{\infty}\frac{(10n+1)^n\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3 9^{2n+1}} \qquad (69)$$

$$\frac{1}{3\pi\sqrt{3}}=\sum_{n=0}^{\infty}\frac{(40n+3)\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3(49)^{2n+1}} \qquad (70)$$

$$\frac{2}{\pi\sqrt{11}}=\sum_{n=0}^{\infty}\frac{(280n+19)\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3(99)^{2n+1}} \qquad (71)$$

$$\frac{1}{2\pi\sqrt{2}}=\sum_{n=0}^{\infty}\frac{(26390n+1103)\left(\frac{1}{2}\right)_n\left(\frac{1}{4}\right)_n\left(\frac{3}{4}\right)_n}{(n!)^3(99)^{4n+2}}. \qquad (72)$$

These equations were first proved by Borwein and Borwein (1987, pp. 177–187). Borwein and Borwein (1987b, 1988, 1993) proved other equations of this type, and Chudnovsky and Chudnovsky (1987) found similar equations for other transcendental constants.

Another identity is

$$\pi^2=36\,\mathrm{Li}_2\left(\tfrac{1}{2}\right)-36\,\mathrm{Li}_2\left(\tfrac{1}{4}\right)-12\,\mathrm{Li}_2\left(\tfrac{1}{8}\right)+6\,\mathrm{Li}_2\left(\tfrac{1}{64}\right), \qquad (73)$$

where L_n is the POLYLOGARITHM. (73) is equivalent to

$$\frac{\pi^2}{36}=\sum_{i=1}^{\infty}\frac{a_i}{2^i i^2} \quad \{a_i\}=[\overline{1,\ -3,\ -2,\ -3,\ 1,\ 0}] \qquad (74)$$

and

$$\pi^2=12L_2\left(\tfrac{1}{2}\right)+6(\ln 2)^2 \qquad (75)$$

(Bailey *et al.* 1995).

A SPIGOT ALGORITHM for π is given by Rabinowitz and Wagon (1995). More amazingly still, a closed form expression giving a DIGIT-EXTRACTION ALGORITHM which produces digits of π (or π^2) in base-16 was recently discovered by Bailey *et al.* (Bailey *et al.* 1995, Adamchik and Wagon 1997),

$$\pi=\sum_{n=0}^{\infty}\left(\frac{4}{8n+1}-\frac{2}{8n+4}-\frac{1}{8n+5}-\frac{1}{8n+6}\right)\left(\frac{1}{16}\right)^n. \qquad (76)$$

This formula, sometimes called the BAILEY-BORWEIN-PLOUFFE ALGORITHM can also be written using the shorthand notation

$$\pi=\sum_{i=1}^{\infty}\frac{p_i}{16^{\lfloor i/8\rfloor}i} \qquad (77)$$

$$\{p_i\}=\{\overline{4,\ 0,\ 0,\ -2,\ -1,\ -1,\ 0,\ 0}\},$$

where $\{p_i\}$ is given by the periodic sequence obtained by appending copies of $\{4,\ 0,\ 0,\ -2,\ -1,\ -1,\ 0,\ 0\}$ (in other words, $p_i \equiv p_{[(i-1)\pmod 8]+1}$ for $i>8$) and $\lfloor x\rfloor$ is the FLOOR FUNCTION. This expression was discovered using the PSLQ ALGORITHM (Ferguson *et al.* 1999) and is equivalent to

$$\pi=\int_0^1\frac{16y-16}{y^4-2y^3+4y-4}\,dy. \qquad (78)$$

A similar formula was subsequently discovered by Ferguson, leading to a 2-D lattice of such formulas which can be generated by these two formulas. A related integral is

$$\pi=\tfrac{22}{7}-\int_0^1\frac{x^4(1-x)^4}{1+x^2}\,dx \qquad (79)$$

(Le Lionnais 1983, p. 22). F. Bellard found the more rapidly converging DIGIT-EXTRACTION ALGORITHM (in HEXADECIMAL)

$$\pi=\frac{1}{2^6}\sum_{n=0}^{\infty}\frac{(-1)^n}{2^{10n}}\left(-\frac{2^5}{4n+1}-\frac{1}{4n+3}+\frac{2^8}{10n+1}-\frac{2^6}{10n+3}-\frac{2}{10n+5}-\frac{2^2}{10n+7}+\frac{1}{10n+9}\right). \qquad (80)$$

This formula can be generalized to

$$\pi=\sum_{k=0}^{\infty}\left(\frac{4+8r}{8k+1}-\frac{8r}{8k+2}-\frac{4r}{8k+3}-\frac{2+8r}{8k+4}-\frac{1+2r}{8k+5}-\frac{1+2r}{8k+6}+\frac{r}{8k+7}\right)\left(\frac{1}{16}\right)^k \qquad (81)$$

for any complex value of r (Adamchik and Wagon), giving the Bailey-Borwein-Plouffe algorithm as the special case $r=0$.

Related formulas are

$$\pi^2=\tfrac{1}{8}\sum_{k=0}^{\infty}\frac{1}{64^k}\left[\frac{144}{(6k+1)^2}-\frac{216}{(6k+2)^2}-\frac{72}{(6k+3)^2}-\frac{54}{(6k+4)^2}+\frac{9}{(6k+5)^2}\right] \qquad (82)$$

and

$$\pi^2 = \sum_{k=0}^{\infty} \frac{1}{16^k} \left[\frac{16}{(8k+1)^2} - \frac{16}{(8k+2)^2} - \frac{8}{(8k+3)^2} - \frac{16}{(8k+4)^2} - \frac{4}{(8k+5)^2} - \frac{4}{(8k+6)^2} + \frac{2}{(8k+7)^2} \right] \quad (83)$$

(Bailey *et al.* 1995, Bailey and Plouffe). More amazingly still, S. Plouffe has devised an algorithm to compute the nth DIGIT of π in any base in $\mathcal{O}(n^3(\log n)^3)$ steps.

A slew of additional identities due to Ramanujan , Catalan, and Newton are given by Castellanos (1988, pp. 86–88), including several involving sums of FIBONACCI NUMBERS. Ramanujan found

$$\sum_{k=0}^{\infty} \frac{(-1)^k (4k+1)[(2k-1)!!]^3}{[(2k)!!]^3} = \sum_{k=0}^{\infty} \frac{(-1)^k (4k+1)\left[\Gamma\left(k+\frac{1}{2}\right)\right]^3}{\pi^{3/2}[\Gamma(k+1)]^3} = \frac{2}{\pi} \quad (84)$$

(Hardy 1923; Hardy 1924; Hardy 1999, p. 7).

Gasper quotes the result

$$\pi = \frac{16}{3} \left[\lim_{x\to\infty} x \,{}_1F_2\left(\tfrac{1}{2};\ 2,\ 3;\ -x^2\right) \right]^{-1}, \quad (85)$$

where ${}_1F_2$ is a GENERALIZED HYPERGEOMETRIC FUNCTION, and transforms it to

$$\pi = \lim_{x\to\infty} 4x \,{}_1F_2\left(\tfrac{1}{2};\ \tfrac{3}{2},\ \tfrac{3}{2};\ -x^2\right), \quad (86)$$

Fascinating results due to Gosper include

$$\lim_{n\to\infty} \prod_{i=n}^{2n} \frac{\pi}{2\tan^{-1} i} = 4^{1/\pi} = 1.554682275\ldots \quad (87)$$

and

$$\sum_{n=1}^{\infty} \frac{1}{n^2} \cos\left(\frac{9}{n\pi + \sqrt{n^2\pi^2 - 9}} \right) = -\frac{\pi^2}{12e^3} = -0.040948222\ldots \quad (88)$$

Gosper also gives the curious identity

$$\frac{1}{e} \prod_{n=1}^{\infty} \left(\frac{1}{3n} + 1 \right)^{3n+1/2} = \frac{3 \cdot 3^{1/24} \sqrt{\left(\frac{1}{3}\right)!}}{2^{5/6} \exp\left[\frac{\gamma}{3} - \frac{\pi\sqrt{3}}{18} + \frac{\sqrt{3}_1\left(\frac{1}{3}\right)}{12\pi} - \frac{2\zeta'(2)}{\pi^2} \right] \pi^{5/6}} = 1.01237855722912\ldots \quad (89)$$

Another curious fact is the ALMOST INTEGER

$$e^\pi - \pi = 19.999099979\ldots, \quad (90)$$

which can also be written as

$$(\pi + 20)^i = -0.9999999992 - 0.0000388927i \approx -1 \quad (91)$$

$$\cos(\ln(\pi + 20)) \approx -0.9999999992. \quad (92)$$

Applying COSINE a few more times gives

$$\cos(\pi \cos(\pi \cos(\ln(\pi + 20)))) \approx -1 + 3.9321609261 \times 10^{-35}. \quad (93)$$

π may also be computed using iterative ALGORITHMS. A quadratically converging ALGORITHM due to Borwein is

$$x_0 = \sqrt{2} \quad (94)$$

$$\pi_0 = 2 + \sqrt{2} \quad (95)$$

$$y_1 = 2^{1/4} \quad (96)$$

and

$$x_{n+1} = \frac{1}{2}\left(\sqrt{x_n} + \frac{1}{\sqrt{x_n}} \right) \quad (97)$$

$$y_{n+1} = \frac{y_n\sqrt{x_n} + \frac{1}{\sqrt{x_n}}}{y_n + 1} \quad (98)$$

$$\pi_n = \pi_{n-1} \frac{x_n + 1}{y_n + 1}. \quad (99)$$

π_n decreases monotonically to π with

$$\pi_n - \pi < 10^{-2+1} \quad (100)$$

for $n \geq 2$. The BRENT-SALAMIN FORMULA is another quadratically converging algorithm which can be used to calculate π. A quadratically convergent algorithm for $\pi/\ln 2$ based on an observation by Salamin is given by defining

$$f(k) = k2^{-k/4} \left[\sum_{n=1}^{\infty} 2^{-k\binom{n}{2}} \right]^2, \quad (101)$$

then writing

$$g_0 \equiv \frac{f(n)}{f(2n)}. \quad (102)$$

Now iterate

$$g_k = \sqrt{\frac{1}{2}\left(g_{k-1} + \frac{1}{g_{k+1}} \right)} \quad (103)$$

to obtain

$$\pi = 2(\ln 2) f(n) \prod_{k=1}^{\infty} g_k. \quad (104)$$

A cubically converging ALGORITHM which converges to the nearest multiple of π to f_0 is the simple iteration

$$f_n = f_{n-1} + \sin(f_{n-1}) \quad (105)$$

(Beeler *et al.* 1972). For example, applying to 23 gives the sequence

$$\{23,\ 22.1537796,\ 21.99186453,\ 21.99114858,\ \ldots\}, \quad (106)$$

which converges to $7\pi \approx 21.99114858$.

A quartically converging ALGORITHM is obtained by letting

$$y_0 = \sqrt{2} - 1 \quad (107)$$

$$\alpha = 6 - 4\sqrt{2}, \quad (108)$$

then defining

$$y_{n+1} = \frac{1 - (1 - y_n^4)^{1/4}}{1 + (1 - y_n^4)^{1/4}} \quad (109)$$

$$\alpha_{n+1} = (1 + y_{n+1})^4 \alpha_n - 2^{2n+3} y_{n+1} (1 + y_{n+1} + y_{n+1}^2). \quad (110)$$

Then

$$\pi = \lim_{n \to \infty} \frac{1}{\alpha_n} \quad (111)$$

and α_n converges to $1/\pi$ quartically with

$$\alpha_n - \frac{1}{\pi} < 16 \cdot 4^n e^{-2\pi \cdot 4^n} \quad (112)$$

(Borwein and Borwein 1987, Bailey 1988, Borwein *et al.* 1989). This ALGORITHM rests on a MODULAR EQUATION identity of order 4.

A quintically converging ALGORITHM is obtained by letting

$$s_0 = 5\left(\sqrt{5} - 2\right) \quad (113)$$

$$\alpha_0 = \tfrac{1}{2}. \quad (114)$$

Then let

$$s_{n+1} = \frac{25}{\left(z + \frac{x}{z} + 1\right)^2 s_n}, \quad (115)$$

where

$$x = \frac{5}{s_n} - 1 \quad (116)$$

$$y = (x - 1)^2 + 7 \quad (117)$$

$$z = \left[\tfrac{1}{2} x \left(y + \sqrt{y^2 - 4x^3}\right)\right]^{1/5}. \quad (118)$$

Finally, let

$$\alpha_{n+1} = s_n^2 \alpha_n - 5^n \left[\tfrac{1}{2}(s_n^2 - 5) + \sqrt{s_n (s_n^2 - 2s_n + 5)}\right], \quad (119)$$

then

$$0 < \alpha_n - \frac{1}{\pi} < 16 \cdot 5^n e^{-\pi 5^n} \quad (120)$$

(Borwein *et al.* 1989). This ALGORITHM rests on a MODULAR EQUATION identity of order 5.

Another ALGORITHM is due to Woon (1995). Define $a(0) \equiv 1$ and

$$a(n) = \sqrt{1 + \left[\sum_{k=0}^{n-1} a(k)\right]^2}. \quad (121)$$

It can be proved by induction that

$$a(n) = \csc\left(\frac{\pi}{2^{n+1}}\right). \quad (122)$$

For $n = 0$, the identity holds. If it holds for $n \le t$, then

$$a(t+1) = \sqrt{1 + \left[\sum_{k=0}^{t} \csc\left(\frac{\pi}{2^{k+1}}\right)\right]^2}, \quad (123)$$

but

$$\csc\left(\frac{\pi}{2^{k+1}}\right) = \cot\left(\frac{\pi}{2^{k+2}}\right) - \cot\left(\frac{\pi}{2^{k+1}}\right), \quad (124)$$

so

$$\sum_{k=0}^{t} \csc\left(\frac{\pi}{2^{k+1}}\right) = \cot\left(\frac{\pi}{2^{t+2}}\right). \quad (125)$$

Therefore,

$$a(t+1) = \csc\left(\frac{\pi}{2^{t+2}}\right), \quad (126)$$

so the identity holds for $n = t + 1$ and, by induction, for all NONNEGATIVE n, and

$$\lim_{n \to \infty} \frac{2^{n+1}}{a(n)} = \lim_{n \to \infty} 2^{n+1} \sin\left(\frac{\pi}{2^{n+1}}\right)$$

$$= \lim_{n \to \infty} 2^{n+1} \frac{\pi}{2^{n+1}} \frac{\sin\left(\frac{\pi}{2^{n+1}}\right)}{\frac{\pi}{2^{n+1}}}$$

$$= \pi \lim_{\theta \to 0} \frac{\sin \theta}{\theta} = \pi. \quad (127)$$

Additional series in which π appears are

$$\tfrac{1}{4}\pi\sqrt{2} = 1 + \tfrac{1}{3} - \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} + \tfrac{1}{11} - \ldots \quad (128)$$

$$\tfrac{1}{4}(\pi - 3) = \frac{1}{2 \cdot 3 \cdot 4} - \frac{1}{4 \cdot 5 \cdot 6} + \frac{1}{6 \cdot 7 \cdot 8} - \ldots \quad (129)$$

$$\frac{\pi^2}{8} = 1 + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \ldots \quad (130)$$

(Wells 1986, p. 53).

Other iterative ALGORITHMS are the ARCHIMEDES ALGORITHM, which was derived by Pfaff in 1800, and the BRENT-SALAMIN FORMULA. Borwein *et al.* (1989) discuss pth order iterative algorithms.

π satisfies the INEQUALITY

$$\left(1 + \frac{1}{\pi}\right)^{\pi+1} \approx 3.14097 < \pi. \quad (131)$$

Pi Heptomino

A HEPTOMINO in the shape of the Greek character PI.

Pi Wordplay

A short mnemonic for remembering the first eight DECIMAL DIGITS of π is "May I have a large container of coffee?" giving 3.1415926 (Gardner 1959; Gardner 1966, p. 92; Eves 1990, p. 122, Davis 1993, p. 9). "But

I must a while endeavour to reckon right" gives nine correct digits (3.1.4159265). A more substantial mnemonic giving 15 digits (3.14159265358979) is "How I want a drink, alcoholic of course, after the heavy lectures involving quantum mechanics," originally due to Sir James Jeans (Gardner 1966, p. 92; Castellanos 1988, p. 152; Eves 1990, p. 122; Davis 1993, p. 9; Blatner 1997, p. 112). A slight extension of this adds the phrase "All of thy geometry, Herr Planck, is fairly hard," giving 24 digits in all (3.14159265358979323846264).

An even more extensive rhyming mnemonic giving 31 digits is "Now I will a rhyme construct, By chosen words the young instruct. Cunningly devised endeavour, Con it and remember ever. Widths in circle here you see, Sketched out in strange obscurity." (Note that the British spelling of "endeavour" is required here.)

The following stanzas are the first part of a poem written by M. Keith based on Edgar Allen Poe's "The Raven." The entire poem gives 740 digits; the fragment below gives only the first 80 (Blatner 1997, p. 113). Words with ten letters represent the digit 0, and those with 11 or more digits are taken to represent two digits.

Poe, E.: Near a Raven.

Midnights so dreary, tired and weary.

Silently pondering volumes extolling all by-now obsolete lore.

During my rather long nap-the weirdest tap!

An ominous vibrating sound disturbing my chamber's antedoor.

'This,' I whispered quietly, 'I ignore.' Perfectly, the intellect remembers: the ghostly fires, a glittering ember.

Inflamed by lightning's outbursts, windows cast penumbras upon this floor. Sorrowful, as one mistreated, unhappy thoughts I heeded:

That inimitable lesson in elegance–Lenore–

Is delighting, exciting... nevermore.

An extensive collection of π mnemonics in many languages is maintained by A. P. Hatzipolakis. Other mnemonics in various languages are given by Castellanos (1988) and Blatner (1997, pp. 112–118).

Keith (1999) considered the set of letters obtained by writing π to base 26 with digits $0=A$, $1=B$, ..., $25=Z$, so that

$$\pi = D.DRSQLOLYRTRODNLHNQTG\ldots.$$

Then the sequence of the first Webster-sanctioned n-letter words in this expression is given by o, lo, rod, trod, steel, oxygen, subplot, ... Additional 6-letter words are: prinky, Libyan, and thingy. The positions of the starting letter of the first n-letter words are 6, 5, 11, 10, 6570, 11582, 115042, ...

Piano Mover's Problem

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Given an open subset U in n-D space and two compact subsets C_0 and C_1 of U, where C_1 is derived from C_0 by a continuous motion, is it possible to move C_0 to C_1 while remaining entirely inside U?

Picard Variety

Let V be a Variety, and write $G(V)$ for the set of divisors, $G_l(V)$ for the set of divisors linearly equivalent to 0, and $G_a(V)$ for the group of divisors algebraically equal to 0. Then $G_a(V)/G_l(V)$ is called the Picard variety. The Albanese variety is dual to the Picard variety.

See also Albanese Variety

Picard's Existence Theorem

If f is a continuous function that satisfies the LIPSCHITZ CONDITION

$$|f(x,\ t)-f(y,\ t)|\leq L|x-y|$$

in a surrounding of $(x_0,\ t_0)\in\Omega\subset\mathbb{R}\times\mathbb{R}^n=\{(x,\ t):|x-x_0|<b,\ |t-t_0|<a\}$, then the differential equation

$$\frac{df}{dx}=f(x,\ t)$$

$$x(t_0)=x_0$$

has a unique solution $x(t)$ in the interval $|t-t_0|<d$, where $d=\min(a,\ b/B)$, min denotes the MINIMUM, $B=\sup|f(t,\ x)|$, and sup denotes the SUPREMUM.

See also LIPSCHITZ CONDITION, ORDINARY DIFFERENTIAL EQUATION

Picard's Great Theorem

Every nonconstant ENTIRE FUNCTION attains every complex value with at most one exception (Apostol 1997). Furthermore, every ANALYTIC FUNCTION assumes every complex value, with possibly one exception, infinitely often in any NEIGHBORHOOD of an ESSENTIAL SINGULARITY.

Picone's Theorem

Let $f(x)$ be integrable in $[-1,\ 1]$, let $(1-x^2)f(x)$ be of bounded variation in $[-1,\ 1]$, let M' denote the least upper bound of $|f(x)(1-x^2)|$ in $[-1,\ 1]$, and let V' denote the total variation of $f(x)(1-x^2)$ in $[-1,\ 1]$. Given the function

$$F(x)=F(-1)+\int_1^x f(x)\,dx,$$

then the terms of its LEGENDRE SERIES

$$F(x)\sim\sum_{n=0}^{\infty}a_nP_n(x)$$

$$a_n = \tfrac{1}{2}(2n+1)\int_{-1}^{1} F(x)P_n(x)\,dx,$$

where $P_n(x)$ is a LEGENDRE POLYNOMIAL, satisfy the inequalities

$$|a_n P_n(x)| < \begin{cases} 8\sqrt{\dfrac{2}{\pi}}\,\dfrac{M'+V'}{(1-\delta^2)^{1/4}}\,n^{-3/2} & \text{for } |x| \leq \delta < 1 \\ 2(M'+V')n^{-1} & \text{for } |x| \leq 1 \end{cases}$$

for $n \geq 1$ (Sansone 1991).

PID

A popular acronym for "PRINCIPAL IDEAL DOMAIN." In engineering circles, the acronym PID refers to the "PROPORTIONAL-INTEGRAL-DERIVATIVE METHOD" algorithm for controlling systems.

See also PRINCIPAL IDEAL DOMAIN, PRINCIPAL IDEAL RING, PROPORTIONAL-INTEGRAL-DERIVATIVE METHOD

Pidduck Polynomial

Polynomials $P_k(x)$ which form the SHEFFER SEQUENCE for

$$g(t) = \frac{2t}{e^t - 1} \tag{1}$$

$$f(t) = \frac{e^t - 1}{e^t + 1} \tag{2}$$

and have GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{P_k(x)}{k!}\,t^k = \frac{t}{1-t}\left(\frac{1+t}{1-t}\right)^x. \tag{3}$$

The first few are

$$P_0(x) = 1$$
$$P_1(x) = 2x + 1$$
$$P_2(x) = 4x^2 4x + 2$$
$$P_3(x) = 8x^3 + 12x^2 + 16x + 6.$$

The Pidduck polynomials are related to the MITTAG-LEFFLER POLYNOMIALS $M_n(x)$ by

$$P_n(x) = \tfrac{1}{2}(e^t + 1)M_n(x) \tag{4}$$

(Roman 1984, p. 127).

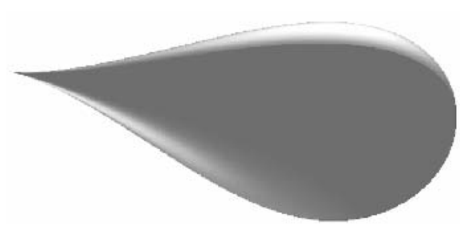
Pine Cone Number
FIBONACCI NUMBER

Piriform

A plane curve also called the PEG TOP and given by the CARTESIAN equation

$$a^4 y^2 = b^2 x^3 (2a - x) \quad (1)$$

and the parametric curves



$$x = a(1 + \sin t) \quad (2)$$

$$y = b \cos t(1 + \sin t) \quad (3)$$

for $t \in [-\pi/2,\ \pi/2]$. It was studied by G. de Longchamps in 1886. The generalization to a QUARTIC 3-D surface

$$\left(x^4 - x^3\right) + y^2 + z^2 = 0, \quad (4)$$

is shown below (Nordstrand).

Pisot Constant
PISOT-VIJAYARAGHAVAN CONSTANT

Pisot-Vijayaraghavan Constant
Let θ be a number greater than 1, λ a POSITIVE number, and

$$\operatorname{frac}(x) \equiv x - \lfloor x \rfloor \quad (1)$$

denote the FRACTIONAL PART of x, where $\lfloor x \rfloor$ is the

FLOOR FUNCTION. Then for a given λ, the sequence of numbers $\mathrm{frac}(\lambda\theta^n)$ for $n = 1, 2, \ldots$ is an EQUIDISTRIBUTED SEQUENCE in the interval (0, 1) when θ does not belong to a λ-dependent exceptional set S of MEASURE ZERO (Koksma 1935). Pisot (1938) and Vijayaraghavan (1941) independently studied the exceptional values of θ, and Salem (1943) proposed calling such values Pisot-Vijayaraghavan numbers.

Pisot (1938) proved that if θ is chosen such that there exists a $\lambda \neq 0$ for which the series

$$\sum_{n=0}^{\infty} \sin^2(\pi\lambda\theta)^n \tag{2}$$

converges, then θ is an ALGEBRAIC INTEGER whose conjugates all (except for itself) have modulus < 1, and λ is an ALGEBRAIC INTEGER of the FIELD $K(\theta)$. Vijayaraghavan (1940) proved that the set of Pisot-Vijayaraghavan numbers has infinitely many LIMIT POINTS.

Salem (1944) proved that the set of Pisot-Vijayaraghavan constants is closed. The proof of this theorem is based on the LEMMA that for a Pisot-Vijayaraghavan constant θ, there always exists a number λ such that $1 \leq \lambda < \theta$ and the following inequality is satisfied,

$$\sum_{n=0}^{\infty} \sin^2(\pi\lambda\theta^n) \leq \frac{\pi^2(2\theta+1)^2}{(\theta-1)^2}. \tag{3}$$

The smallest Pisot-Vijayaraghavan constant is given by the POSITIVE ROOT $\theta_0 \approx 1.32372$ of

$$x^3 - x - 1 = 0. \tag{4}$$

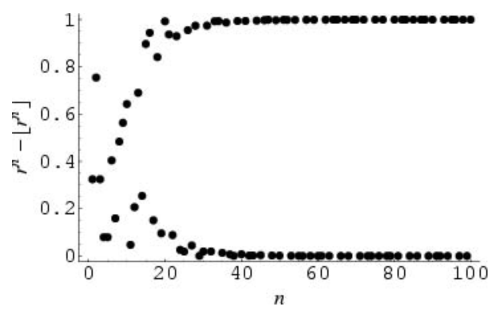
This number was identified as the smallest known by Salem (1944), and proved to be the smallest possible by Siegel (1944). Siegel also identified the next smallest Pisot-Vijayaraghavan constant θ_1 as the root of

$$x^4 - x^3 - 1 = 0. \tag{5}$$

showed that θ_1 and θ_2 are isolated in S, and showed that the roots of each POLYNOMIAL

$$x^n\left(x^2 - x - 1\right) + x^2 - 1 \quad n = 1, 2, 3, \ldots \tag{6}$$

$$x^n - \frac{x^{n+1}-1}{x^2-1} \quad n = 3, 5, 7, \ldots \tag{7}$$



$$x^n - \frac{x^{n-1}-1}{x-1} \quad n = 3, 5, 7, \ldots \tag{8}$$

belong to S, where $\theta_0 = \phi$ (the GOLDEN MEAN) is the accumulation point of the set (in fact, the smallest; Le Lionnais 1983, p. 40).

Some small Pisot-Vijayaraghavan constants and their POLYNOMIALS are given in the following table. The latter two entries are from Boyd (1977).

k	number	order	POLYNOMIAL
0	1.3247179572	3	1 0 -1 -1
1	1.3802775691	4	1 -1 0 0 -1
	1.6216584885	16	1 -2 2 -3 2 -2 1 0 0 1 -1 2 -2 2 -2 1 -1
	1.8374664495	20	1 -2 0 1 -1 0 1 -1 0 1 0 -1 0 1 -1 0 1 -1 0 1 -1

All the points in S less than ϕ are known (Dufresnoy and Pisot 1955). Each point of S is a limit point from both sides of the set T of SALEM CONSTANTS (Salem 1945).

Pisot-Vijayaraghavan constants give rise to ALMOST INTEGERS. For example, the larger the power to which θ_0 is taken, the closer $\theta_0^n - \lfloor\theta_0^n\rfloor$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION, is to either 0 or 1 (Trott 2000). The powers of θ_0 for which this quantity is closer to 0 are 1, 3, 4, 5, 6, 7, 8, 11, 12, 14, 17, ... (Sloane's A051016), and those for which it is closer to 1 are 2, 9, 10, 13, 15, 16, 18, 20, 21, 23, ... (Sloane's A051017).

Pitchfork Bifurcation

Let $f : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ be a one-parameter family of C^3 maps satisfying

$$f(-x,\ \mu) = -f(x,\ \mu) \tag{1}$$

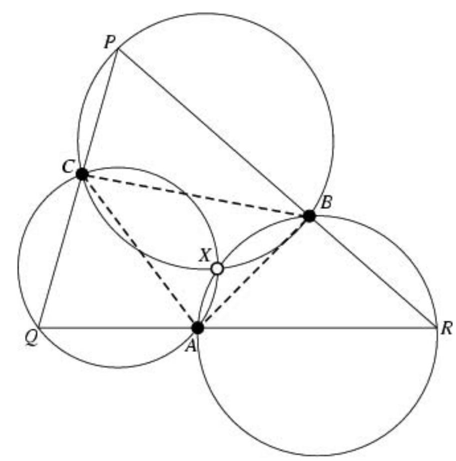
$$\left[\frac{\partial f}{\partial x}\right]_{\mu=0,\ x=0} = 0 \tag{2}$$

$$\left[\frac{\partial^2 f}{\partial x\,\partial \mu}\right]_{0,\ 0} > 0 \tag{3}$$

$$\left[\frac{\partial^3 f}{\partial \mu^3}\right]_{\mu=0,\ x=0} < 0. \tag{4}$$

(Actually, condition (1) can be relaxed slightly.) Then there are intervals having a single stable fixed point and three fixed points (two of which are stable and one of which is unstable). This BIFURCATION is called a pitchfork bifurcation. An example of an equation displaying a pitchfork bifurcation is

$$\dot{x} = \mu x - x^3 \tag{5}$$



(Guckenheimer and Holmes 1997, p. 145).

Pivot Theorem

If the VERTICES A, B, and C of TRIANGLE ΔABC lie on sides QR, RP, and PQ of the TRIANGLE ΔPQR, then the three CIRCUMCIRCLES CBP, ACQ, and BAR have a common point X. In extended form, this theorem becomes MIQUEL'S THEOREM.

Pivoting

The element in the diagonal of a matrix by which other elements are divided in an algorithm such as GAUSS-JORDAN ELIMINATION is called the pivot element. Partial pivoting is the interchanging of rows and full pivoting is the interchanging of both rows and columns in order to place a particularly "good"

element in the diagonal position prior to a particular operation.

See also GAUSS-JORDAN ELIMINATION

Pizza Theorem

If a circular pizza is divided into 8, 12, 16, ...slices by making cuts at equal angles from an arbitrary point, then the sums of the areas of alternate slices are equal.

There is also a second pizza theorem. This one gives the VOLUME of a pizza of thickness a and RADIUS z,

$$pizza.$$

Place (Digit)

DIGIT

Place (Field)

A place v of a NUMBER FIELD k is an ISOMORPHISM class of field maps k onto a dense subfield of a nondiscrete locally compact FIELD k_v.

In the function field case, let F be a function field of algebraic functions of one variable over a FIELD K. Then by a place in F, we mean a subset p of F which is the IDEAL of nonunits of some VALUATION RING O over K.

van der Waerden, B. L. *Algebra, 2 vols.* New York: Springer-Verlag, 1991.

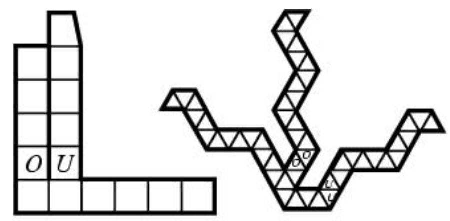
Place (Game)

For n players, $n-1$ games are needed to fairly determine first place, and $n-1+1g(n-1)$ are needed to fairly determine first and second place.

Place (Riemann Sphere)

The word "place" has a special meaning in complex variables, where it roughly corresponds to a point in the COMPLEX PLANE (except that it reflects the Riemann sheet structure imposed by whatever function is under discussion). For example, if the function in question is $\ln z$, then 1 and $e^{2\pi i}$ are different places.

Plaindrome



A plaindrome is a number whose HEXADECIMAL digits are in nondecreasing order. The first few are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 17, 18, 19, 20, 21, 22, 23, 24, ... (Sloane's A023757). The first few which are not plaindromes are 16, 32, 33, 48, 49, 50, 64, ..., corresponding to 10_{16}, 20_{16}, 21_{16}, 30_{16}, 31_{16}, 32_{16}, 64_{16}, ...

Planar Bubble Problem

BUBBLE

Planar Connected Graph

A planar connected graph is a GRAPH which is both planar and connected. The numbers of planar con-

nected graphs with $n = 1, 2, \ldots$ nodes are 1, 1, 1, 2, 6, 20, 99, ... (Sloane's A003094; Steinbach 1990, p. 131). A subset of planar 3-connected graphs are called POLYHEDRAL GRAPHS.

The following table gives the numbers of planar connected graphs having minimal degrees of at least k.

k	Sloane	$n = 1, 2, 3, \ldots$
2	A054381	0, 0, 1, 3, 10, 49, 332, ...

The numbers of planar connected graphs with $n = 1, 2, \ldots$ edges are 1, 1, 3, 5, 12, 30, 79, 227, 709, 2318, ... (Sloane's A046091).

See also CONNECTED GRAPH, PLANAR GRAPH, POLYHEDRAL GRAPH, POLYNEMA

Planar Distance

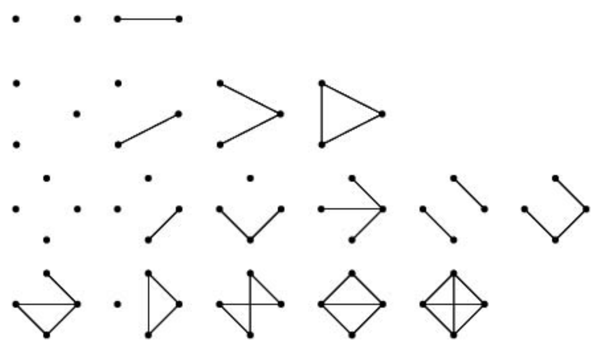
For n points in the PLANE, there are at least

$$N_1 = \sqrt{n - \tfrac{3}{4}} - \tfrac{1}{2}$$

different DISTANCES. The minimum DISTANCE can occur only $\leq 3n - 6$ times, and the MAXIMUM DISTANCE can occur $\leq n$ times. Furthermore, no DISTANCE can occur as often as

$$N_2 = \tfrac{1}{4} n \left(1 + \sqrt{8n - 7}\right) < \frac{n^{3/2}}{\sqrt{2}} - \frac{n}{4}$$

times.



Finally, no set of $n > 6$ points in the PLANE can determine only ISOSCELES TRIANGLES.

Planar Graph

A GRAPH is planar if it can be drawn in a PLANE without EDGES crossing (i.e., it has CROSSING NUMBER 0). The number of planar graphs with $n = 1, 2, \ldots$ nodes are 1, 2, 4, 11, 33, 142, ... (Sloane's A005470; Wilson 1975, p. 162).

There are a number of efficient algorithms for planarity testing, which are unfortunately all difficult to implement. Most are based on the $o(n^3)$ algorithm of Auslander and Parter (1961; Skiena 1990, p. 247). One implementation is given by `PlanarQ[`g`]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``), which however should be trusted for only versions 4.1 and higher.

Only planar graphs have DUALS and if G is planar, then G has VERTEX DEGREE ≤ 5. A graph is planar IFF it has a COMBINATORIAL DUAL GRAPH (Harary 1994, p. 115). Any planar graph has a GRAPH EMBEDDING as a PLANAR STRAIGHT LINE GRAPH where edges do not intersect (Fáry 1948; Bryant 1989; Skiena 1990, pp. 100 and 251; Scheinerman and Wilf 1994).

COMPLETE GRAPHS are planar only for $n \leq 4$. The complete BIPARTITE GRAPH $K(3, 3)$ is nonplanar. More generally, Kuratowski proved in 1930 that a graph is planar IFF it does not contain within it any graph which can be CONTRACTED to the pentagonal graph $K(5)$ or the hexagonal graph $K(3, 3)$. K_5 can be decomposed into a union of two planar graphs, giving it a "DEPTH" of $E(K_5) = 2$. Simple CRITERIA for determining the depth of graphs are not known. Beineke and Harary (1964, 1965) have shown that if $n \not\equiv 4 \pmod 6$, then

$$E(K_n) = \left\lfloor \tfrac{1}{6}(n + 7) \right\rfloor.$$

The DEPTHS of the graphs K_n for $n = 4$, 10, 22, 28, 34, and 40 are 1, 3, 4, 5, 6, and 7 (Meyer 1970).

All TREES are planar, as is a CYCLE GRAPH, GRID GRAPH, or WHEEL GRAPH. Every planar graph on nine vertices has a nonplanar complement (Battle *et al.* 1962; Skiena 1990, p. 250).

The following table gives the numbers of planar graphs having minimal degrees of at least k.

k	Sloane	$n = 1, 2, 3, ...$
2	A049370	0, 0, 1, 3, 10, 50, 335, ...
3	A049371	0, 0, 0, 1, 2, 9, 46, 386, ...
4	A049372	0, 0, 0, 0, 0, 1, 1, 4, 14, 69, ...
5	A049373	0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1, 1, 5, ...

Planar Point

A point $\mathbf{p}$ on a REGULAR SURFACE $M \in \mathbb{R}^3$ is said to be planar if the GAUSSIAN CURVATURE $K(\mathbf{p}) = 0$ and $S(\mathbf{p}) = 0$ (where S is the SHAPE OPERATOR), or equivalently, both of the PRINCIPAL CURVATURES κ_1 and κ_2 are 0.

See also ANTICLASTIC, ELLIPTIC POINT, GAUSSIAN CURVATURE, HYPERBOLIC POINT, PARABOLIC POINT, SYNCLASTIC

References

Gray, A. *Modern Differential Geometry of Curves and Surfaces with Mathematica, 2nd ed.* Boca Raton, FL: CRC Press, p. 375, 1997.

Planar Polygon

Flat polygons embedded in 3-D space can be transformed into a congruent planar polygon as follows. First, translate the starting vertex to (0, 0, 0) by subtracting it from each vertex of the polygon. Then find the normal $\mathbf{n}$ to the polygon by taking the CROSS PRODUCT of the first and last vertices. Now, let $\mathbf{A}$ be the rotation matrix for EULER ANGLES ψ, θ, and ϕ, and solve

$$\mathsf{A}\begin{bmatrix} n_x \\ n_y \\ \sqrt{1-n_x^2-n_y^2} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \tag{1}$$

for $\cos\psi$ and $\cos\theta$ (after first expressing sines in terms of cosines using $\cos x = \sqrt{1-\sin^2 x}$. The result is

$$\phi = \pm\frac{n_y}{\sqrt{n_x^2+n_y^2}} \tag{2}$$

$$\theta = \pm\sqrt{1 - n_x^2 - n_y^2}. \quad (3)$$

The signs are chosen as follows:

$$\psi = \cos^{-1}\left[-\operatorname{sgn}(n_x)\frac{n_y}{\sqrt{n_x^2 + n_y^2}}\right] \quad (4)$$

$$\theta = \cos^{-1}\left[-\operatorname{sgn}(n_x n_z)\sqrt{1 - n_x^2 - n_y^2}\right]. \quad (5)$$

Plugging these back in and applying to the original polygon then gives a polygon whose vertices all have one component zero. This component can then be dropped. The only special cases which need to be taken into account are $|n_z| = 1$, in which case the polygon is parallel to the xy-plane and the third components can be immediately dropped. The second occurs when $n_x = 0$, in which case there is no component of the normal vector along the X-AXIS, so the Euler rotation will not work. However, simply picking a different starting vertex from which to calculate the normal resolves this degenerate case.

See also POLYGON

Planar Space

Let (ξ_1, ξ_2) be a locally EUCLIDEAN coordinate system. Then

$$ds^2 = d\xi_1^2 + d\xi_2^2. \quad (1)$$

Now plug in

$$d\xi_1 = \frac{\partial \xi_1}{\partial x_1}\,dx_1 + \frac{\partial \xi_1}{\partial x_2}\,dx_2 \quad (2)$$

$$d\xi_2 = \frac{\partial \xi_2}{\partial x_1}\,dx_1 + \frac{\partial \xi_2}{\partial x_2}\,dx_2 \quad (3)$$

to obtain

$$\begin{aligned} ds^2 = {} & \left[\left(\frac{\partial \xi_1}{\partial x_1}\right)^2 + \left(\frac{\partial \xi_2}{\partial x_1}\right)^2\right] dx_1^2 \\ & + 2\left[\frac{\partial \xi_1}{\partial x_1}\frac{\partial \xi_1}{\partial x_2} + \frac{\partial \xi_2}{\partial x_1}\frac{\partial \xi_2}{\partial x_2}\right] dx_1\,dx_2 \\ & + \left[\left(\frac{\partial \xi_1}{\partial x_2}\right)^2 + \left(\frac{\partial \xi_2}{\partial x_2}\right)^2\right] dx_2^2. \end{aligned} \quad (4)$$

Reading off the COEFFICIENTS from

$$ds^2 = g_{11}\,dx_1^2 + 2g_{12}\,dx_1\,dx_2 + g_{22}(dx_2)^2 \quad (5)$$

gives

$$g_{11} = \left(\frac{\partial \xi_1}{\partial x_1}\right)^2 + \left(\frac{\partial \xi_2}{\partial x_1}\right)^2 \quad (6)$$

$$g_{12} = \frac{\partial \xi_1}{\partial x_1}\frac{\partial \xi_1}{\partial x_2} + \frac{\partial \xi_2}{\partial x_1}\frac{\partial \xi_2}{\partial x_2} \quad (7)$$

$$g_{22} = \left(\frac{\partial \xi_1}{\partial x_2}\right)^2 + \left(\frac{\partial \xi_2}{\partial x_2}\right)^2. \quad (8)$$

Making a change of coordinates $(x_1, x_2) \to (x_1', x_2')$ gives

$$\begin{aligned} g_{11}' &= \left(\frac{\partial \xi_1}{\partial x_1'}\right)^2 + \left(\frac{\partial \xi_2}{\partial x_1'}\right)^2 \\ &= \left(\frac{\partial \xi_1}{\partial x_1}\frac{\partial x_1}{\partial x_1'} + \frac{\partial \xi_1}{\partial x_2}\frac{\partial x_2}{\partial x_1'}\right)^2 + \left(\frac{\partial \xi_2}{\partial x_1}\frac{\partial x_1}{\partial x_1'} + \frac{\partial \xi_2}{\partial x_2}\frac{\partial x_2}{\partial x_1'}\right)^2 \\ &= g_{11}\left(\frac{\partial x_1}{\partial x_1'}\right)^2 + 2g_{12}\frac{\partial x_1}{\partial x_1'}\frac{\partial x_2}{\partial x_1'} + g_{22}\left(\frac{\partial x_2}{\partial x_1'}\right)^2 \end{aligned} \quad (9)$$

$$\begin{aligned} g_{12}' &= \frac{\partial \xi_1}{\partial x_1}\frac{\partial x_1}{\partial x_1'}\frac{\partial \xi_1}{\partial x_2}\frac{\partial x_2}{\partial x_2'} + \frac{\partial \xi_2}{\partial x_1}\frac{\partial x_1}{\partial x_1'}\frac{\partial \xi_2}{\partial x_2}\frac{\partial x_2}{\partial x_2'} \\ &= g_{12}\frac{\partial x_1}{\partial x_1'}\frac{\partial x_2}{\partial x_2'} \end{aligned} \quad (10)$$

$$g_{22}' = g_{11}\left(\frac{\partial x_1}{\partial x_1'}\right)^2 + 2g_{12}\frac{\partial x_1}{\partial x_2'}\frac{\partial x_2}{\partial x_2'} + g_{22}\left(\frac{\partial x_2}{\partial x_2'}\right)^2. \quad (11)$$

Planar Straight Line Graph

A GRAPH EMBEDDING of a PLANAR GRAPH in which only straight line segments are used to connect the VERTICES. Fáry (1948) showed that every PLANAR GRAPH has an EMBEDDING which is a planar straight line graph with noncrossing edges (Bryant 1989; Skiena 1990, pp. 100 and 251; Schneinerman and Wilf 1994). de Fraysseix *et al.* (1988) give an algorithm for constructing a planar straight line for a graph of order n by placing the vertices on a $(2n - 4) \times (n - 2)$ grid (Skiena 1990, p. 251).

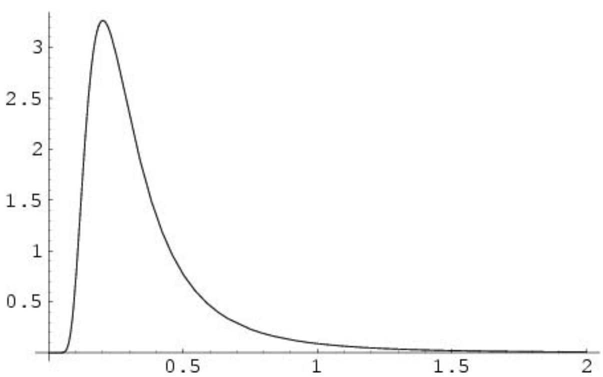
Plancherel's Theorem



$$\int_{-\infty}^{\infty} f(x)\bar{g}(x)\,dx = \int_{-\infty}^{\infty} F(s)\bar{G}(s)\,ds,$$

where $F(s) \equiv \mathcal{F}[f(x)]$ and $\mathcal{F}$ denotes a Fourier transform and $\bar{z}$ is the complex conjugate. If f and g are real

$$\int_{-\infty}^{\infty} f(x)g(-x)\,dx = \int_{-\infty}^{\infty} F(s)G(s)\,ds.$$

See also Fourier Transform, Parseval's Theorem

Planck's Radiation Function

The function

$$f(x) = \frac{15}{\pi^4} \frac{1}{x^5(e^{1/x} - 1)}, \tag{1}$$

which is normalized so that

$$\int_0^{\infty} f(x)\,dx = 1. \tag{2}$$

The first and second raw moments are

$$\mu_1' = \frac{30\zeta(3)}{\pi^4} \tag{3}$$

$$\mu_2' = \frac{5}{2\pi^2}, \tag{4}$$

but higher order raw moments do not exist since the corresponding integrals do not converge.
It has a maximum at $x \approx 0.201405$, where

$$f'(x) = \frac{5x - e^{1/x}(5x - 1)}{x^7(e^{1/x} - 1)^2} = 0, \tag{5}$$

and inflection points at $x \approx 0.11842$ and $x \approx 0.283757$, where

$$f''(x) = \frac{e^{1/x}\left(1 + e^{1/x}\right) + 6x\left(e^{1/x} - 1\right)\left[e^{1/x}(5x - 2) - 5x\right]}{\left(e^{1/x} - 1\right)^3 x^9} = 0. \tag{6}$$

Plane

A plane is a 2-D doubly ruled surface spanned by two linearly independent vectors. The generalization of the plane to higher dimensions is called a hyperplane. The angle between two intersecting planes is known as the dihedral angle.

In intercept form, a plane passing through the points $(a, 0, 0)$, $(0, b, 0)$ and $(0, 0, c)$ is given by

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1. \tag{1}$$

The equation of a plane perpendicular to the nonzero vector $\hat{\mathbf{n}} = (a, b, c)$ through the point (x_0, y_0, z_0) is

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} \cdot \begin{bmatrix} x - x_0 \\ y - y_0 \\ z - z_0 \end{bmatrix} = a(x - x_0) + b(y - y_0) + c(z - z_0) = 0, \tag{2}$$

so

$$ax + by + cz + d = 0. \tag{3}$$

where

$$d \equiv -ax_0 - by_0 - cz_0. \tag{4}$$

A plane specified in this form therefore has x-, y-, and z-intercepts at

$$x = -\frac{d}{a} \tag{5}$$

$$y = -\frac{d}{b} \tag{6}$$

$$z = -\frac{d}{c}, \tag{7}$$

and lies at a DISTANCE

$$h = \frac{|d|}{\sqrt{a^2 + b^2 + c^2}} \tag{8}$$

from the ORIGIN.

The plane through P_1 and parallel to (a_1, b_1, c_1) and (a_2, b_2, c_2) is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \end{vmatrix} = 0. \tag{9}$$

The plane through points P_1 and P_2 parallel to direction (a, b, c) is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ a & b & c \end{vmatrix} = 0. \tag{10}$$

The three-point form is

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = \begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ x_3 - x_1 & y_3 - y_1 & z_3 - z_1 \end{vmatrix} = 0. \tag{11}$$

The POINT-PLANE DISTANCE from a point (x_0, y_0, z_0) to a plane

$$ax + by + cz + d = 0 \tag{12}$$

is

$$D = \frac{ax_0 + by_0 + cz_0 + d}{\pm\sqrt{a^2 + b^2 + c^2}}. \tag{13}$$

The DIHEDRAL ANGLE between the planes

$$A_1x + B_1y + C_1z + D_1 = 0 \tag{14}$$

$$A_2x + B_2y + C_2z + D_2 = 0 \tag{15}$$

which have normal vectors $\mathbf{N}_1 = (A_1, B_1, C_1)$ and $\mathbf{N}_2 = (A_2, B_2, C_2)$ is simply given via the DOT PRODUCT of the normals,

$$\cos\theta = \mathbf{N}_1 \cdot \mathbf{N}_2$$

$$= \frac{A_1A_2 + B_1B_2 + C_1C_2}{\sqrt{A_1^2 + B_1^2 + C_1^2}\sqrt{A_2^2 + B_2^2 + C_2^2}}. \tag{16}$$

In order to specify the relative distances of $n > 1$ points in the plane, $1 + 2(n-2) = 2n - 3$ coordinates are needed, since the first can always be placed at (0, 0) and the second at $(x, 0)$, where it defines the X-AXIS. The remaining $n - 2$ points need two coordinates each. However, the total number of distances is

$$_nC_2 = \binom{n}{2} = \frac{n!}{2!(n-2)!} = \tfrac{1}{2}n(n-1), \tag{17}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, so the distances between points are subject to m relationships, where

$$m \equiv \tfrac{1}{2}n(n-1) - (2n-3) = \tfrac{1}{2}(n-2)(n-3). \tag{18}$$

For $n = 2$ and $n = 3$, there are no relationships. However, for a QUADRILATERAL (with $n = 4$), there is one (Weinberg 1972).

It is impossible to pick random variables which are uniformly distributed in the plane (Eisenberg and Sullivan 1996). In 4-D, it is possible for four planes to intersect in exactly one point. For every set of n points in the plane, there exists a point O in the plane having the property such that *every* straight line through O has at least 1/3 of the points on each side of it (Honsberger 1985).

Every RIGID MOTION of the plane is one of the following types (Singer 1995):

1. ROTATION about a fixed point P.
2. TRANSLATION in the direction of a line l.
3. REFLECTION across a line l.
4. Glide-reflections along a line l.

Every RIGID MOTION of the hyperbolic plane is one of the previous types or a

5. Horocycle rotation.

Plane Chart

EQUIRECTANGULAR PROJECTION

Plane Curve

A CURVE which lies in a single PLANE. A plane curve may be closed or open. Curves which are interesting

for some reason and whose properties have therefore been investigates are called "special" curves (Lawrence 1972). Some of the most common open curves are the LINE, PARABOLA, and HYPERBOLA, and some of the most common closed curves are the CIRCLE and ELLIPSE.

Plane Graph

PLANAR GRAPH

Plane Partition

5	4	2	1	1
3	2			
2	2			

A two-dimensional array of INTEGERS nonincreasing both left to right and top to bottom which add up to a given number, i.e., $n_{ij} \geq n_{i(j+1)}$ and $n_{ij} \geq n_{(i+1)j}$. For example, a planar partition of 22 is illustrated above. The GENERATING FUNCTION for the number $\mathrm{PL}(n)$ of planar partitions of n is

$$\sum_{n=0}^{\infty} \mathrm{PL}(n)x^n = \frac{1}{\prod_{k=1}^{\infty}(1-x^k)^k}$$

$$= 1 + x + 3x^2 + 6x^3 + 13x^4 + 24x^5 + \ldots \quad (1)$$

(Sloane's A000219, MacMahon 1912b, Speciner 1972, Bender and Knuth 1972, Bressoud and Propp 1999). MacMahon (1960) also showed that the number of plane partitions $\mathrm{PL}(a,\ b,\ c)$ whose YOUNG DIAGRAMS fit inside an $a \times b \times c$ box is given by

$$\mathrm{PL}(a,\ b,\ c) = \prod_{i=1}^{a}\prod_{j=1}^{b}\prod_{k=1}^{c}\frac{i+j+k-1}{i+j+k-2} \quad (2)$$

(Bressoud and Propp 1999, Fulmek and Krattenthaler 2000). Expanding out the products gives

$$\mathrm{PL}(a,\ b,\ c) = \prod_{i=1}^{a}\frac{\Gamma(i)\Gamma(b+c+i)}{\Gamma(b+i)\Gamma(c+i)} \quad (3)$$

$$= \frac{G(a+1)G(b+1)G(c+1)G(a+b+c+1)}{G(a+b+1)G(a+c+1)G(b+c+1)}, \quad (4)$$

where $G(n)$ is BARNES' G-FUNCTION. Taking $n=a=b=c$ gives

$$\mathrm{PL}(n,\ n,\ n) = \prod_{i=1}^{n}\frac{\Gamma(i)\Gamma(i+2n)}{[\Gamma(i+n)]^2} \quad (5)$$

$$= \frac{[G(n+1)]^3 G(3n+1)}{[G(2n+1)]^3}, \quad (6)$$

the first few terms of which are 2, 20, 980, 232848, 267227532, 1478619421136, ... (Sloane's A008793).

Amazingly, PL(a, b, c) also gives the number of HEXAGON TILINGS by RHOMBI for a hexagon of side lengths a, b, c, a, b, c (David and Tomei 1989, Fulmek and Krattenthaler 2000).

The concept of planar partitions can also be generalized to cubic partitions.

Plane-Filling Curve

Plane-Filling Function

Plane-Filling Function

A SPACE-FILLING FUNCTION which maps a 1-D INTERVAL into a 2-D area. Plane-filling functions were thought to be impossible until Hilbert discovered the HILBERT CURVE in 1891.

Plane-filling functions are often (imprecisely) defined to be the "limit" of an infinite sequence of specified curves which "fill" the PLANE without "HOLES," hence the more popular term PLANE-FILLING CURVE. The term "plane-filling function" is preferable to "PLANE-FILLING CURVE" because "curve" informally connotes "GRAPH" (i.e., range) of some continuous function, but the GRAPH of a plane-filling function is a solid patch of 2-space with no evidence of the order in which it was traced (and, for a dense set, retraced). Actually, all that is needed to rigorously define a plane-filling function is an arbitrarily refinable correspondence between contiguous subintervals of the domain and contiguous subareas of the range.

True plane-filling functions are not ONE-TO-ONE. In fact, because they map closed intervals onto closed areas, they cannot help but overfill, revisiting at least twice a dense subset of the filled area. Thus, every point in the filled area has *at least* one inverse image.

Plane-Line Intersection

Line-Plane Intersection

Planted Planar Tree

A planted plane tree (V, E, v, α) is defined as a vertex set V, edges set E, ROOT v, and order relation α on V which satisfies

1. For $x, y \in V$ if $\rho(x) < \rho(y)$, then $x \propto y$, where $\rho(x)$ is the length of the path from v to x,
2. If $\{r, s\}, \{x, y\} \in E$, $\rho(r) = \rho(x) = \rho(s) - 1 = \rho(y) - 1$ and $r \propto x$, then $s \propto y$

(Klarner 1969, Chorneyko and Mohanty 1975). The CATALAN NUMBERS give the number of planar trivalent planted trees.

Plate Carre

EQUIRECTANGULAR PROJECTION

Plateau Curves

A curve studied by the Belgian physicist and mathematician Joseph Plateau. It has Cartesian equation

$$x = \frac{a\ \sin[(m+n)t]}{\sin[(m-n)t]}$$

$$y = \frac{2a\ \sin(mt)\sin(nt)}{\sin[(m-n)t]}.$$

If $m = 2n$, the Plateau curve degenerates to a CIRCLE with center $(1, 0)$ and radius 2.

Plateau's Laws

BUBBLES can meet only at ANGLES of 120° (for two BUBBLES) and 109°28′16″ (for three BUBBLES), where the exact value of 109.5° is the TETRAHEDRAL DIHEDRAL ANGLE. This was proved by Jean Taylor using MEASURE THEORY to study AREA minimization. The DOUBLE BUBBLE is AREA minimizing, but it is not known if the triple BUBBLE is also AREA minimizing. It is also unknown if empty chambers trapped inside can minimize AREA for $n \geq 3$ BUBBLES.

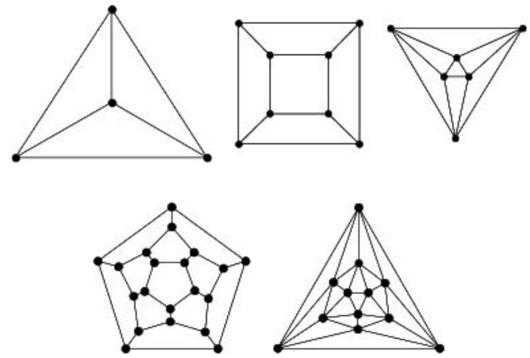
Taylor, J. E. "The Structure of Singularities in Soap-Bubble-Like and Soap-Film-Like Minimal Surfaces." *Ann. Math.* **103**, 489–539, 1976.

Plateau's Problem

The problem in CALCULUS OF VARIATIONS to find the MINIMAL SURFACE of a boundary with specified constraints (usually having no singularities on the surface). In general, there may be one, multiple, or no MINIMAL SURFACES spanning a given closed curve in space. The EXISTENCE of a solution to the general case was independently proven by Douglas (1931) and Radó (1933), although their analysis could not exclude the possibility of singularities. Osserman (1970) and Gulliver (1973) showed that a minimizing solution *cannot* have singularities.



The problem is named for the Belgian physicist who solved some special cases experimentally using soap films and wire frames (Isenberg 1992, Wells 1991). The illustration above shows the 13-polygon surface obtained for a cubical wire frame.

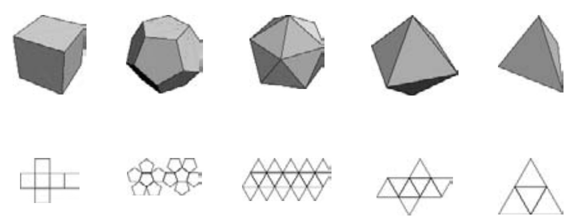
Platonic Graph



A POLYHEDRAL GRAPH corresponding to the SKELETON of a PLATONIC SOLID. The five platonic graphs, the TETRAHEDRAL GRAPH, CUBICAL GRAPH, OCTAHEDRAL GRAPH, DODECAHEDRAL GRAPH, and ICOSAHEDRAL GRAPH, are illustrated above. They are special cases of SCHLEGEL GRAPHS.

See also PLATONIC SOLID, POLYHEDRAL GRAPH, SCHLEGEL GRAPH

References

Bondy, J. A. and Murty, U. S. R. *Graph Theory with Applications.* New York: North Holland, p. 234, 1976.

Platonic Solid

The Platonic solids, also called the regular solids or regular polyhedra, are CONVEX POLYHEDRA with equivalent faces composed of congruent CONVEX REGULAR POLYGONS. There are exactly five such solids (Steinhaus 1983, pp. 252–256): the CUBE, DODECAHEDRON, ICOSAHEDRON, OCTAHEDRON, and TETRAHEDRON, as was proved by Euclid in the last proposition of the *ELEMENTS*. The Platonic solids are sometimes also called "cosmic figures" (Cromwell 1997), although this term is sometimes used to refer collectively to both the Platonic solids *and* KEPLER-POINSOT SOLIDS (Coxeter 1973).

The Platonic solids were known to the ancient Greeks, and were described by Plato in his *Timaeus* ca. 350 BC. In this work, Plato equated the TETRAHEDRON with the "element" fire, the CUBE with earth,

the ICOSAHEDRON with water, the OCTAHEDRON with air, and the DODECAHEDRON with the stuff of which the constellations and heavens were made (Cromwell 1997).

If P is a POLYHEDRON with congruent (convex) regular polygonal faces, then Cromwell (1997, pp. 77–78) shows that the following statements are equivalent.

1. The vertices of P all lie on a SPHERE.
2. All the DIHEDRAL ANGLES are equal.
3. All the VERTEX FIGURES are REGULAR POLYGONS.
4. All the SOLID ANGLES are equivalent.
5. All the vertices are surrounded by the same number of FACES.

Let v (sometimes denoted N_0) be the number of VERTICES, e (or N_1) the number of EDGES, and f (or N_2) the number of FACES. The following table gives the SCHLÄFLI SYMBOL, WYTHOFF SYMBOL, and C&R symbol, the number of vertices v, edges e, and faces f, and the POINT GROUPS for the Platonic solids (Wenninger 1989).

Solid	SCHLÄFLI SYMBOL	WYTHOFF SYMBOL	C&R Symbol	v	e	f	Group
CUBE	$\{4, 3\}$	$3 \mid 2\ 2\ 4$	4^3	8	12	6	O_h
DODECAHEDRON	$\{5, 3\}$	$3 \mid 2\ 2\ 5$	5^3	20	30	12	I_h
ICOSAHEDRON	$\{3, 5\}$	$5 \mid 2\ 2\ 3$	3^5	12	30	20	I_h
OCTAHEDRON	$\{3, 4\}$	$4 \mid 2\ 2\ 3$	3^4	6	12	8	O_h
TETRAHEDRON	$\{3, 3\}$	$3 \mid 2\ 2\ 3$	3^3	4	6	4	T_d

The duals of Platonic solids are other Platonic solids and, in fact, the dual of the TETRAHEDRON is another TETRAHEDRON. Let r be the INRADIUS, ρ the MIDRADIUS, and R the CIRCUMRADIUS of a given Platonic solid. Then

$$rR = \rho^2.$$

The following two tables give the analytic and numerical values of these distances for Platonic solids with unit side length.

Solid	r	ρ	R
CUBE	$\frac{1}{2}$	$\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{3}$
DODECAHEDRON	$\frac{1}{20}\sqrt{250+110\sqrt{5}}$	$\frac{1}{4}(3+\sqrt{5})$	$\frac{1}{4}(\sqrt{15}+\sqrt{3})$
ICOSAHEDRON	$\frac{1}{12}(3\sqrt{3}+\sqrt{15})$	$\frac{1}{4}(1+\sqrt{5})$	$\frac{1}{4}\sqrt{10+2\sqrt{5}}$
OCTAHEDRON	$\frac{1}{6}\sqrt{6}$	$\frac{1}{2}$	$\frac{1}{2}\sqrt{2}$
TETRAHEDRON	$\frac{1}{12}\sqrt{6}$	$\frac{1}{4}\sqrt{2}$	$\frac{1}{4}\sqrt{6}$

Solid	r	ρ	R
CUBE	0.5	0.70711	0.86603
DODECAHEDRON	1.11352	1.30902	1.40126
ICOSAHEDRON	0.75576	0.80902	0.95106
OCTAHEDRON	0.40825	0.5	0.70711
TETRAHEDRON	0.20412	0.35355	0.61237

Finally, let A be the AREA of a single FACE, V be the VOLUME of the solid, the EDGES be of unit length on a side, and α be the DIHEDRAL ANGLE. The following table summarizes these quantities for the Platonic solids.

Solid	A	V	α
Cube	1	1	$\frac{1}{2}\pi$
Dodecahedron	$\frac{1}{4}\sqrt{25+10\sqrt{5}}$	$\frac{1}{4}(15+7\sqrt{5})$	$\cos^{-1}\left(-\frac{1}{5}\sqrt{5}\right)$
Icosahedron	$\frac{1}{4}\sqrt{3}$	$\frac{5}{12}(3+\sqrt{5})$	$\cos^{-1}\left(-\frac{1}{3}\sqrt{5}\right)$
Octahedron	$\frac{1}{4}\sqrt{3}$	$\frac{1}{3}\sqrt{2}$	$\cos^{-1}\left(-\frac{1}{3}\right)$
Tetrahedron	$\frac{1}{4}\sqrt{3}$	$\frac{1}{12}\sqrt{2}$	$\cos^{-1}\left(\frac{1}{3}\right)$

The number of EDGES meeting at a VERTEX is $2e/v$. The SCHLÄFLI SYMBOL can be used to specify a Platonic solid. For the solid whose faces are p-gons (denoted $\{p\}$), with q touching at each VERTEX, the symbol is $\{p, q\}$. Given p and q, the number of VERTICES, EDGES, and faces are given by

$$N_0 = \frac{4p}{4-(p-2)(q-2)}$$

$$N_1 = \frac{2pq}{4-(p-2)(q-2)}$$

$$N_2 = \frac{4q}{4-(p-2)(q-2)}.$$

The plots above show scaled duals of the Platonic solid embedded in a CUMULATED form of the original solid, where the scaling is chosen so that the dual

edges lie at the incenters of the original faces (Wenninger 1983, pp. 8–9).

Since the Platonic solids are convex, the CONVEX HULL of each Platonic solid is the solid itself. MINIMAL SURFACES for Platonic solid frames are illustrated in Isenberg (1992, pp. 82–83).

Plethysm

A group theoretic operation which is useful in the study of complex atomic spectra. A plethysm takes a set of functions of a given symmetry type $\{\mu\}$ and forms from them symmetrized products of a given degree r and other symmetry type $\{\nu\}$. A plethysm

$$\{\mu\}\otimes\{\nu\}=\sum\{\lambda\}$$

satisfies the rules

$$A\otimes(BC)=(A\otimes B)(A\otimes C)=A\otimes BA\otimes C,$$

$$A\otimes(B\pm C)=A\otimes B\pm A\otimes C$$

$$(A\otimes B)\otimes C=A\otimes(B\otimes C)$$

$$(A+B)\otimes\{\lambda\}=\sum\Gamma_{\mu\nu\lambda}(A\otimes\{\mu\})(B\otimes\{\nu\}),$$

where $\Gamma_{\mu\nu\lambda}$ is the coefficient of $\{\lambda\}$ in $\{\mu\}\{\nu\}$,

$$(A-B)\otimes\{\lambda\}=\sum(-1)^r\Gamma_{\mu\nu\lambda}(A\otimes\{\mu\})(B\otimes\{\tilde{\nu}\}),$$

where $\{\tilde{\nu}\}$ is the partition of r conjugate to $\{\nu\}$, and

$$(AB)\otimes\{\lambda\}=\sum g_{\mu\nu\lambda}(A\otimes\{\mu\})(B\otimes\{\nu\}),$$

where $g_{\mu\nu\lambda}$ is the coefficient of $\{\lambda\}$ in the inner product $\{\mu\}\circ(\nu\}$ (Wybourne 1970).

Plot

GRAPH (FUNCTION)

Plot3D

GRAPH (FUNCTION)

Plouffe's Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Define the function

$$\rho(x)\equiv\begin{cases}1 & \text{for } x<0\\ 0 & \text{for } x\geq 0.\end{cases}\qquad(1)$$

Let

$$a_n=\sin(2^n)=\begin{cases}\sin 1 & \text{for } n=0\\ 2a_0\sqrt{1-a_0^2} & \text{for } n=1\\ 2a_{n-1}(1-2a_{n-2}^2) & \text{for } n\geq 2,\end{cases}\qquad(2)$$

then

$$\sum_{n=0}^{\infty}\frac{\rho(a_n)}{2^{n+1}}=\frac{1}{2\pi}.\qquad(3)$$

For

$$b_n=\cos(2^n)=\begin{cases}\cos 1 & \text{for } n=0\\ 2b_{n-1}^2-1 & \text{for } n\geq 1,\end{cases}\qquad(4)$$

and

$$\sum_{n=0}^{\infty}\frac{\rho(b_n)}{2^{n+1}}=0.4756260767\ldots.\qquad(5)$$

Letting

$$c_n=\tan(2^n)=\begin{cases}\tan 1 & \text{for } n=0\\ \dfrac{2c_{n-1}}{1-c_{n-1}^2} & \text{for } n\geq 1,\end{cases}\qquad(6)$$

then

$$\sum_{n=0}^{\infty}\frac{\rho(c_n)}{2^{n+1}}=\frac{1}{\pi}.\qquad(7)$$

Plouffe asked if the above processes could be "inverted." He considered

$$\alpha_n=\sin\left(2^n\ \sin^{-1}\tfrac{1}{2}\right)$$

$$=\begin{cases}\tfrac{1}{2} & \text{for } n=0\\ \tfrac{1}{2}\sqrt{3} & \text{for } n=1\\ 2\alpha_{n-1}(1-2\alpha_{n-2}^2) & \text{for } n\geq 2,\end{cases}\qquad(8)$$

giving

$$\sum_{n=0}^{\infty}\frac{\rho(\alpha_n)}{2^{n+1}}=\tfrac{1}{12},\qquad(9)$$

and

$$\beta_n=\cos\left(2^n\ \cos^{-1}\tfrac{1}{2}\right)=\begin{cases}\tfrac{1}{2} & \text{for } n=0\\ 2\beta_{n-1}^2-1 & \text{for } n\geq 1,\end{cases}\qquad(10)$$

giving

$$\sum_{n=0}^{\infty} \frac{\rho(\beta_n)}{2^{n+1}} = \tfrac{1}{2}, \tag{11}$$

and

$$\gamma_n = \tan\left(2^n \tan^{-1} \tfrac{1}{2}\right) = \begin{cases} \tfrac{1}{2} & \text{for } n=0 \\ \dfrac{2\gamma_{n-1}}{1-\gamma_{n-1}^2} & \text{for } n \geq 1, \end{cases} \tag{12}$$

giving

$$\sum_{n=0}^{\infty} \frac{\rho(\alpha_n)}{2^{n+1}} = \frac{1}{\pi} \tan^{-1}\left(\tfrac{1}{2}\right). \tag{13}$$

The latter is known as Plouffe's constant (Plouffe 1997). The positions of the 1s in the BINARY expansion of this constant are 3, 6, 8, 9, 10, 13, 21, 23, ... (Sloane's A004715).

Borwein and Girgensohn (1995) extended Plouffe's γ_n to *arbitrary* REAL x, showing that if

$$\xi_n = \tan(2^n \tan^{-1} x) = \begin{cases} x & \text{for } n=0 \\ \dfrac{2\xi_{n-1}}{1-\xi_{n-1}^2} & \text{for } n \geq 1 \text{ and } |\xi_{n-1}| \neq 1 \\ -\infty & \text{for } n \geq 1 \text{ and} |\xi_{n-1}|=1, \end{cases} \tag{14}$$

then

$$\sum_{n=0}^{\infty} \frac{\rho(\xi_n)}{2^{n+1}} = \begin{cases} \dfrac{\tan^{-1} x}{\pi} & \text{for } x \geq 0 \\ 1 + \dfrac{\tan^{-1} x}{\pi} & \text{for } x < 0. \end{cases} \tag{15}$$

Borwein and Girgensohn (1995) also give much more general recurrences and formulas.

Plücker Relations

PLÜCKER'S EQUATIONS

Plücker's Conoid

A RULED SURFACE sometimes also called the CYLINDROID. von Seggern (1993) gives the general functional form as

$$ax^2 + by^2 - zx^2 - zy^2 = 0, \tag{1}$$

whereas Fischer (1986) and Gray (1997) give

$$z = \frac{2xy}{(x^2+y^2)}. \tag{2}$$

A polar parameterization therefore gives

$$x(r, \theta) = r \cos\theta \tag{3}$$

$$y(r, \theta) = r \sin\theta \tag{4}$$

$$z(r, \theta) = 2 \cos\theta \sin\theta. \tag{5}$$

A generalization of Plücker's conoid to n folds is given by

$$x(r, \theta) = r \cos \theta \quad (6)$$

$$y(r, \theta) = r \sin \theta \quad (7)$$

$$z(r, \theta) = \sin(n\theta) \quad (8)$$

(Gray 1997). The cylindroid is the inversion of the CROSS-CAP (Pinkall 1986).

Range, R. M. and Anderson, R. W. "Hans-Joachim Bremermann, 1926–1996." *Not. Amer. Math. Soc.* **43**, 972–976, 1996.

Plus

The ADDITION of two quantities, i.e., a plus b. The operation is denoted $a+b$, and the symbol $+$ is called the PLUS SIGN. Floating point ADDITION is sometimes denoted $\oplus$.

See also ADDITION, MINUS, PLUS OR MINUS, TIMES

Plus or Minus

The symbol $\pm$ is used to denote a quantity which should be both added and subtracted, as in $a \pm b$. The symbol can be used to denote a range of uncertainty, or to denote a pair of quantities, such as the roots given by the QUADRATIC FORMULA

$$x\pm = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

When order is relevant, the symbol $a \mp b$ is also used, so an expression OF THE FORM $x \pm y \mp z$ is interpreted as $x+y-z$ or $x-y+z$. In contrast, the expression $x \pm y \pm z$ is interpreted to mean the set of four quantities $x+y+z$, $x-y+z$, $x+y-z$, and $x-y-z$.

Plutarch Numbers

In *Moralia,* the Greek biographer and philosopher Plutarch states "Chrysippus says that the number of compound propositions that can be made from only ten simple propositions exceeds a million. (Hipparchus, to be sure, refuted this by showing that on the affirmative side there are 103,049 compound statements, and on the negative side 310,952.)" These numbers are known as the Plutarch numbers.

103,049 can be interpreted as the number s_{10} of BRACKETINGS on ten letters (Stanley 1997, Habsieger *et al.* 1998). Similarly, Plutarch's second number is given by $(s_{10}+s_{11})/2=310,954$ (Habsieger *et al.* 1998).

Pochhammer Symbol

The Pochhammer symbol

$$(x)_n \equiv \frac{\Gamma(x+n)}{\Gamma(x)} = x(x+1)\cdots(x+n-1) = \frac{\Gamma(x+n)}{\Gamma(x)} \quad (1)$$

(Abramowitz and Stegun 1972, p. 256; Spanier 1987; Koepf 1998, p. 5) for $n \geq 0$ is an unfortunate notation used in the theory of special functions for the RISING FACTORIAL, which is denoted $x^{(n)}$ (Roman 1984, p. 5) or $\langle x \rangle_n$ (Comtet 1974, p. 6) in combinatorics. In combinatorial usage, $(x)_n$ denotes the FALLING FACTORIAL. Extreme caution is therefore needed in interpreting the notations $(x)_n$ and $x^{(n)}$.

The Pochhammer symbol $(x)_n$ obeys the transformation due to Euler

$$\sum_{n=0}^{\infty} \frac{(a)_n}{n!} a_n z^n = (1-z)^{-a} \sum_{n=0}^{\infty} \frac{(a)_n}{n!} \Delta^n a_0 \left(\frac{z}{1-z}\right)^n, \quad (2)$$

where Δ is the FORWARD DIFFERENCE and

$$\Delta^k a_0 = \sum_{m=0}^{k} (-1)^m \binom{k}{m} a_{k-m} \quad (3)$$

(Nørlund 1955).

The sum of $1/(k)_p$ can be done in closed form as

$$\sum_{k=1}^{n} \frac{1}{(k)_p} = \frac{1}{(p-1)\Gamma(p)} - \frac{n\Gamma(n)}{(p-1)\Gamma(n+p)} \quad (4)$$

for $p > 1$.

Pocklington-Lehmer Test

POCKLINGTON'S THEOREM

Pocklington's Criterion

Let p be an ODD PRIME, k be an INTEGER such that $p \nmid k$ and $1 \leq k \leq 2(p+1)$, and

$$N \equiv 2kp+1.$$

Then the following are equivalent

1. N is PRIME.
2. $\text{GCD}(a^k+1, N) = 1$,

where GCD is the GREATEST COMMON DENOMINATOR. This is a modified version of the original theorem due to Lehmer.

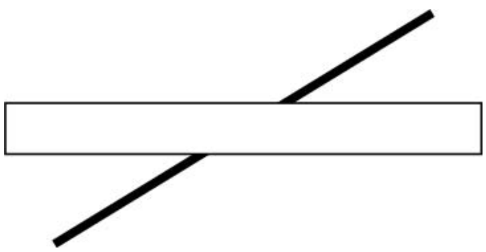
References

Pocklington, H. C. "The Determination of the Prime or Composite Nature of Large Numbers by Fermat's Theorem." *Proc. Cambridge Phil. Soc.* **18**, 29–30, 1914/16.

Pocklington's Theorem

Let $n-1=FR$ where F is the factored part of a number

$$F=p_1^{a_1}\cdots p_r^{a_r}, \tag{1}$$



where $(R, F)=1$, and $R<\sqrt{n}$. If there exists a b_i for $i=1, ..., r$ such that

$$b_i^{n-1}\equiv 1 \pmod{n} \tag{2}$$

$$\mathrm{GCD}\left(b_i^{(n-1)/p_i}-1,\ n\right)=1, \tag{3}$$

then n is a PRIME.

Poggendorff Illusion

The illusion that the two ends of a straight LINE SEGMENT passing behind an obscuring RECTANGLE are offset when, in fact, they are aligned. The Poggendorff illusion was discovered in 1860 by physicist and scholar J. C. Poggendorff, editor of *Annalen der Physik und Chemie*, after receiving a letter from astronomer F. Zöllner. In his letter, Zöllner described an illusion he noticed on a fabric design in which parallel lines intersected by a pattern of short diagonal lines appear to diverge (ZÖLLNER'S ILLUSION). Pondering this illusion, Poggendorff noticed and described another illusion resulting from the apparent misalignment of a diagonal line; an illusion which today bears his name (IllusionWorks).

Pohlke's Theorem

The principal theorem of AXONOMETRY, first published without proof by Pohlke in 1860. It states that three segments of arbitrary length $a'x'$, $a'y'$, and $a'z'$ which are drawn in a PLANE from a point a' under arbitrary ANGLES form a parallel projection of three equal segments ax, ay, and az from the ORIGIN of three PERPENDICULAR coordinate axes. However, only one of the segments or one of the ANGLES may vanish.

Poincaré Conjecture

The conjecture that every SIMPLY CONNECTED 3-MANIFOLD is HOMEOMORPHIC to the 3-SPHERE. This conjecture was first proposed in 1904 by H. Poincaré (Poincaré 1953, pp. 486 and 498), and subsequently generalized to the conjecture that every COMPACT n-MANIFOLD is HOMOTOPY-equivalent to the n-sphere IFF it is HOMEOMORPHIC to the n-SPHERE. The generalized statement reduces to the original conjecture for $n=3$.

The $n=1$ case of the generalized conjecture is trivial, the $n=2$ case is classical, $n=3$ remains open, $n=4$

was proved by Freedman (1982) (for which he was awarded the 1986 FIELDS MEDAL), $n = 5$ by Zeeman (1961), $n = 6$ by Stallings (1962), and $n \geq 7$ by Smale in 1961. Smale subsequently extended his proof to include $n \geq 5$.

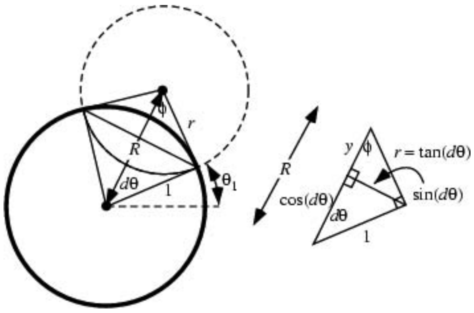
Poincaré Group

LORENTZ GROUP

Poincaré Hyperbolic Disk



A 2-D space having HYPERBOLIC GEOMETRY defined as the DISK $\{x \in \mathbb{R}^2 : |x| < 1\}$, with HYPERBOLIC METRIC

$$ds^2 = \frac{dx^2 + dy^2}{(1 - r^2)^2}. \tag{1}$$

The Poincaré disk is a model for HYPERBOLIC GEOMETRY in which a line is REPRESENTED AS an ARC of a CIRCLE whose ends are PERPENDICULAR to the DISK's

boundary (and DIAMETERS are also permitted). Two arcs which do not meet correspond to parallel rays, arcs which meet orthogonally correspond to PERPENDICULAR lines, and arcs which meet on the boundary are a pair of limits rays.

The endpoints of any arc can be specified by two angles around the disk θ_1 and θ_2. Define

$$\theta \equiv \tfrac{1}{2}(\theta_1 + \theta_2) \quad (2)$$

$$d\theta \equiv \tfrac{1}{2}|\theta_1 - \theta_2| \quad (3)$$

Then trigonometry shows that in the above diagram,

$$r = \tan(d\theta) \quad (4)$$

$$y = \sin(d\theta)\tan(d\theta), \quad (5)$$

so the radius of the circle forming the arc is

$$R = \cos(d\theta) + y = \sec(d\theta) \quad (6)$$

and its center is located at $R(\cos\theta, \sin\theta)$. The half-angle subtended by the arc is then

$$\sin\phi = \frac{\sin(d\theta)}{\tan(d\theta)} = \cos(d\theta), \quad (7)$$

so

$$\phi = \sin^{-1}[\cos(d\theta)]. \quad (8)$$

The Poincaré hyperbolic disk represents a CONFORMAL MAP, so angles between rays can be measured directly. There is an ISOMORPHISM between the Poincaré disk model and the KLEIN-BELTRAMI MODEL.

Poincaré Separation Theorem

Let $\{\mathbf{y}^k\}$ be a set of orthonormal vectors with $k = 1, 2, ..., K$, such that the INNER PRODUCT $(\mathbf{y}^k, \mathbf{y}^k) = 1$. Then set

$$\mathbf{x} = \sum_{k=1}^{K} u_k \mathbf{y}^k \quad (1)$$

so that for any SQUARE MATRIX A for which the product $\mathsf{A}\mathbf{x}$ is defined, the corresponding QUADRATIC FORM is

$$(\mathbf{x}, \mathsf{A}\mathbf{x}) = \sum_{k,l=1}^{K} u_k u_l \left(\mathbf{y}^k, \mathsf{A}\mathbf{y}^l\right) \quad (2)$$

Then if

$$\mathbf{B}_k = \left(\mathrm{y}^k, \mathsf{A}\mathbf{y}^l\right) \quad (3)$$

for $k, l = 1, 2, ..., K$, it follows that

$$\lambda_i(\mathbf{B}_K) \le \lambda_1(\mathsf{A}) \quad (4)$$

$$\lambda_{K-j}(\mathbf{B}_K) \ge \lambda_{N-j}(\mathsf{A}) \quad (5)$$

for $i = 1, 2, ..., K$ and $j = 0, 1, ..., K-1$.

Poincaré-Bertrand Theorem

For $s_1, s_2 = \pm 1$,

$$\lim_{\substack{\epsilon_1 \to 0 \\ \epsilon_2 \to 0}} \frac{1}{x_1 - is_1\epsilon_1} \frac{1}{x_2 - is_2\epsilon_2}$$

$$= \left[PV\left(\frac{1}{x_1}\right) + i\pi s_1 \delta(x_1)\right]\left[PV\left(\frac{1}{x_2}\right) + i\pi s_2 \delta(x_2)\right]$$

$$+\pi^2\delta(x_1)\delta(x_2), \quad (1)$$

where $\delta(x)$ is the DELTA FUNCTION and PV denotes the CAUCHY PRINCIPAL VALUE.

See also DELTA FUNCTION

Poincaré-Birkhoff Fixed Point Theorem

For the rational curve of an unperturbed system with ROTATION NUMBER r/s under a map T (for which every point is a FIXED POINT of T^s), only an even number of FIXED POINTS $2ks$ ($k = 1, 2, ...$) will remain under perturbation. These FIXED POINTS are alternately stable (ELLIPTIC) and unstable (HYPERBOLIC). Around each elliptic fixed point there is a simultaneous application of the Poincaré-Birkhoff fixed point theorem and the KAM THEOREM, which leads to a self-similar structure on all scales.

The original formulation was: Given a CONFORMAL ONE-TO-ONE transformation from an ANNULUS to itself that advances points on the outer edge positively and on the inner edge negatively, then there are at least two fixed points.

It was conjectured by Poincaré from a consideration of the three-body problem in celestial mechanics and proved by Birkhoff.

Poincaré-Birkhoff-Witt Theorem

Every LIE ALGEBRA L is isomorphic to a SUBALGEBRA of some LIE ALGEBRA A^-, where the ASSOCIATIVE ALGEBRA A may be taken to be the linear operators over a VECTOR SPACE V.

Poincaré-Hopf Index Theorem

The index of a VECTOR FIELD with finitely many zeros on a compact, oriented MANIFOLD is the same as the EULER CHARACTERISTIC of the MANIFOLD.

See also GAUSS-BONNET FORMULA

Poincaré's Holomorphic Lemma

Solutions to HOLOMORPHIC differential equations are themselves HOLOMORPHIC FUNCTIONS of time, initial conditions, and parameters.

See also POINCARÉ'S LEMMA

Poincaré's Lemma

Poincaré's lemma says that on a CONTRACTIBLE MANIFOLD, all CLOSED FORMS are EXACT. While $d^2 = 0$ implies that all exact forms are closed, it is not always true that all closed forms are exact. The Poincaré lemma is used to show that closed forms represent COHOMOLOGY CLASSES.

See also COHOMOLOGY, COHOMOLOGY CLASS, CLOSED FORM, DE RHAM COHOMOLOGY, DIFFERENTIAL FORM, EXACT FORM, EXTERIOR DERIVATIVE, MANIFOLD, POINCARÉ'S HOLOMORPHIC LEMMA, STOKES' THEOREM, WEDGE PRODUCT

Poincaré's Theorem

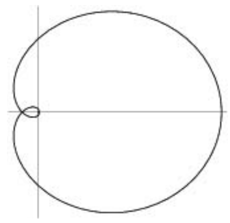
If $\nabla \times \mathbf{F} = 0$ (i.e., $\mathbf{F}(\mathbf{x})$ is an IRROTATIONAL FIELD) in a simply connected neighborhood $U(\mathbf{x})$ of a point $\mathbf{x}$, then in this neighborhood, $\mathbf{F}$ is the GRADIENT of a SCALAR FIELD $\phi(\mathbf{x})$,

$$\mathbf{F}(\mathbf{x}) = -\nabla\phi(\mathbf{x}) \quad (1)$$

for $\mathbf{x} \in U(\mathbf{x})$, where ∇ is the gradient operator. Consequently, the GRADIENT THEOREM gives

$$\int_\sigma \mathbf{F} \cdot ds = \phi(\mathbf{x}_1) - \phi(\mathbf{x}_2) \quad (2)$$

for any path σ located completely within $U(\mathbf{x})$, starting at $\mathbf{x}_1$ and ending at $\mathbf{x}_2$.



This means that if $\nabla \times \mathbf{F} = 0$, the LINE INTEGRAL of $\mathbf{F}$ is path-independent.

Point

A 0-DIMENSIONAL mathematical object which can be specified in n-D space using n coordinates. Although the notion of a point is intuitively rather clear, the mathematical machinery used to deal with points and point-like objects can be surprisingly slippery. This difficulty was encountered by none other than Euclid himself who, in his *ELEMENTS*, gave the vague definition of a point as "that which has no part."

The basic geometric structures of higher DIMENSIONAL geometry–the LINE, PLANE, SPACE, and HYPERSPACE–are all built up of infinite numbers of points arranged in particular ways.

The DECIMAL POINT in a DECIMAL EXPANSION is voiced as "point" in the United States, e.g., 3.1415 is voiced "three point one four one five," whereas a COMMA is used for this purpose in continental Europe.

Point at Infinity

P is the point on the line AB such that $\overline{PA}/\overline{PB} = 1$. It can also be thought of as the point of intersection of two PARALLEL lines. In 1639, Desargues (1864) became the first to consider the point at infinity (Cremona 1960, p. ix), although Poncelet was the first to systematically employ the point at infinity (Graustein 1930).

The term point at infinity is also used for COMPLEX INFINITY (Krantz 1999, p. 82).

Point Circle

Members of a COAXAL SYSTEM satisfy

$$x^2 + y^2 + 2\lambda x + c = (x+\lambda)^2 + y^2 + c - \lambda^2 = 0$$

for values of λ. Picking $\lambda^2 = c$ then gives the two circles

$$\left(x \pm \sqrt{c}\right)^2 + y^2 = 0$$

of zero RADIUS, known as point circles. The two point circles $(\pm\sqrt{c},\ 0)$, real or imaginary, are called the LIMITING POINTS of the COAXAL SYSTEM.

See also COAXAL SYSTEM, LIMITING POINT

Durell, C. V. *Modern Geometry: The Straight Line and Circle.* London: Macmillan, p. 123, 1928.

Point Connectivity

VERTEX CONNECTIVITY

Point Distances

The maximum distance between n points in 3-D can occur no more than $2n-2$ times. Also, there exists a fixed number c such that no distance determined by a set of n points in 3-D space occurs more than $cn^{5/3}$ times. The maximum distance can occur no more than $\left\lfloor \frac{1}{4}n^2 \right\rfloor$ times in 4-D, where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

Point Estimation Theory

A theory of constructing initial conditions that provides safe convergence of a numerical root-finding algorithm for an equation $f(z)=0$. Point estimation theory treats convergence conditions and the domain of convergence using only information about f at the initial point z_0 (Petkovic *et al.* 1997, p. 1). An initial point that provides safe convergence of NEWTON'S METHOD is called an APPROXIMATE ZERO.

Point estimation theory should not be confusion with POINT ESTIMATORS of probability theory.

See also ALPHA-TEST, APPROXIMATE ZERO, NEWTON'S METHOD, POINT ESTIMATOR

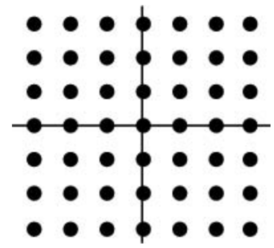
Point Estimator

An ESTIMATOR of the actual values of population.

See also POINT ESTIMATION THEORY

Point Groups



A point group is a group of symmetry operations which all leave at least one point unmoved. Although an isolated object may have an arbitrary SCHÖNFLIES SYMBOL, the requirement that symmetry be present in a lattice requires that only 1, 2, 3, and 6-fold symmetry axes are possible (the CRYSTALLOGRAPHY RESTRICTION), which restricts the number of possible so-called CRYSTALLOGRAPHIC POINT GROUPS to 32.

See also CRYSTALLOGRAPHIC POINT GROUPS, CRYSTALLOGRAPHY RESTRICTION, SCHÖNFLIES SYMBOL, SPACE GROUPS

Hahn, T. (Ed.). *International Tables for Crystallography, vol. A, 4th ed.* Dordrecht, Netherlands: Kluwer, p. 752, 1995.

Point Lattice

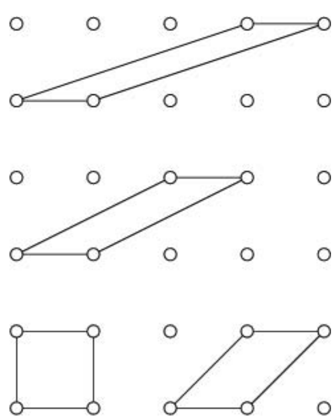
A regularly spaced array of points falling along regularly spaced line. The grid lines can be oriented to form unit cells in the shape of a square, rectangle, hexagon, etc. However, unless otherwise specified, point lattices are generally taken to refer to points in a square array, i.e., points with coordinates $(m, n, \cdots)$, where m, n, ... are INTEGERS. Such an array is often called a GRID or a MESH. Point lattices are frequently simply called "lattices," which unfortunately conflicts with the same term applied to ordered sets treated in LATTICE THEORY.

Formally, a lattice is a DISCRETE SUBGROUP of EUCLIDEAN SPACE, assuming it contains the origin. That is, a lattice is closed under addition and inverses, and every point has a neighborhood in which it is the only lattice point. The common examples are $\mathbb{Z} \subset \mathbb{R}$ and $\mathbb{Z}^2 \subset \mathbb{R}^2$. Usually, a lattice is defined to have full rank, i.e., a lattice in $\mathbb{R}^n$ is the SUBGROUP

$$\{a_1 v_1 + \cdots a_n v_n\}, \tag{1}$$

where the a_i are integers and v_i are LINEARLY INDEPENDENT vectors. Note that a lattice needs at most n elements to generate it. For example, the subgroup $\{a_1 + a_2\sqrt{2}\} \subset \mathbb{R}$ requires two generators but is not DISCRETE, and is not a lattice. The above illustration shows that the subgroup generated by 1 and $1/\sqrt{2}$ is not a lattice by showing $a + b/\sqrt{2}$ for successive $b \in [0, 1]$.

The FRACTION of lattice points VISIBLE from the ORIGIN, as derived in Castellanos (1988, pp. 155–156), is



$$\frac{N'(r)}{N(r)} = \frac{\frac{24}{\pi^2}r^2 + \mathcal{O}(r \ln r)}{4r^2 + \mathcal{O}(r)}$$
$$= \frac{\frac{6}{\pi^2} + \mathcal{O}\left(\frac{\ln r}{r}\right)}{1 + \mathcal{O}\left(\frac{1}{r}\right)}$$
$$= \frac{6}{\pi^2}. \quad (2)$$

Therefore, this is also the probability that two randomly picked integers will be RELATIVELY PRIME to one another.

For $2 \leq n \leq 32$, it is possible to select $2n$ lattice points with $x, y \in [1, n]$ such that no three are in a straight LINE. The number of distinct solutions (not counting reflections and rotations) for $n = 1, 2, \ldots$, are 1, 1, 4, 5, 11, 22, 57, 51, 156 ... (Sloane's A000769). For large n, it is conjectured that it is only possible to select at most $(c + \epsilon)n$ lattice points with no three COLLINEAR, where

$$c = \left(2\pi^2/3\right)^{1/3} \approx 1.87 \quad (3)$$

(Guy and Kelly 1968; Guy 1994, p. 242). The number of the n^2 lattice points $x, y \in [1, n]$ which can be picked with no four CONCYCLIC is $\mathcal{O}(n^{2/3} - \epsilon)$ (Guy 1994, p. 241).

Any PARALLELOGRAM on the lattice in which two opposite sides each have length 1 has unit area (Hilbert and Cohn-Vossen 1999, pp. 33–34).

A special set of POLYGONS defined on the regular lattice are the GOLYGONS. A NECESSARY and SUFFICIENT condition that a linear transformation transforms a lattice to itself is that it be UNIMODULAR. M. Ajtai has shown that there is no efficient ALGORITHM for finding any fraction of a set of spanning vectors in a lattice having the shortest lengths unless there is an efficient algorithm for all of them (of which none is known). This result has potential applications to cryptography and authentication (Cipra 1996).

Point Probability

The portion of the probability distribution which has a P-VALUE *equal to* the observed P-VALUE.

See also TAIL PROBABILITY

Point-Line Distance—2-D

Given a line $ax+by+c=0$ and a point (x_0, y_0), in slope-intercept form, the equation of the line is

$$y=-\frac{a}{b}x-\frac{c}{b}, \tag{1}$$

so the line has SLOPE $-a/b$. Points on the line have the vector coordinates

$$\begin{bmatrix} x \\ -\frac{a}{b}x-\frac{c}{d} \end{bmatrix}=\begin{bmatrix} 0 \\ -\frac{c}{d} \end{bmatrix}-\frac{1}{b}\begin{bmatrix} -b \\ a \end{bmatrix}x. \tag{2}$$

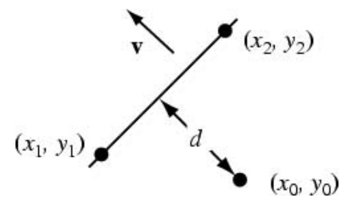
Therefore, the VECTOR

$$\begin{bmatrix} -b \\ a \end{bmatrix} \tag{3}$$

is PARALLEL to the line, and the VECTOR

$$\mathbf{v}=\begin{bmatrix} a \\ b \end{bmatrix} \tag{4}$$

is PERPENDICULAR to it. Now, a VECTOR from the point to the line is given by



$$\mathbf{r}=\begin{bmatrix} x-x_0 \\ y-y_0 \end{bmatrix} \tag{5}$$

Projecting $\mathbf{r}$ onto $\mathbf{v}$,

$$d=|\mathrm{proj}_{\mathbf{v}}\mathbf{r}|=\frac{|\mathbf{v}\cdot\mathbf{r}|}{\mathbf{v}}=|\hat{\mathbf{v}}\cdot\mathbf{r}|=\frac{|a(x-x_0)+b(y-y_0)|}{\sqrt{a^2+b^2}}$$

$$=\frac{|ax+by-ax_0-by_0|}{\sqrt{a^2+b^2}}$$

$$=\frac{|ax_0+by_0+c|}{\sqrt{a^2+b^2}}. \tag{6}$$

If the line is represented by the endpoints of a VECTOR (x_1, y_1) and (x_2, y_2), then the PERPENDICULAR VECTOR is

$$\mathbf{v}=\begin{bmatrix} y_2-y_1 \\ -(x_2-x_1) \end{bmatrix} \tag{7}$$

$$\hat{\mathbf{v}}=\frac{1}{s}\begin{bmatrix} y_2-y_1 \\ -(x_2-x_1) \end{bmatrix}, \tag{8}$$

where

$$s=|\mathbf{v}|=\sqrt{(x_2-x_1)^2+(y_2-y_1)^2}, \tag{9}$$

so the distance is

$$d=|\hat{\mathbf{v}}\cdot\mathbf{r}|=\frac{|(y_2-y_1)(x_0-x_1)-(x_2-x_1)(y_0-y_1)|}{\sqrt{(x_2-x_1)^2+(y_2-y_1)^2}}. \tag{10}$$

The distance from a point (x_0, y_0) to the line $y=a+bx$ can also be computed using simple VECTOR algebra. Let $\mathbf{L}$ be a VECTOR in the same direction as the line

$$\mathbf{L}=\begin{bmatrix} x \\ a+bx \end{bmatrix}-\begin{bmatrix} 0 \\ a \end{bmatrix}=\begin{bmatrix} x \\ bx \end{bmatrix} \tag{11}$$

$$\hat{\mathbf{L}}=\frac{1}{\sqrt{b^2+1}}\begin{bmatrix} 1 \\ b \end{bmatrix}. \tag{12}$$

A given point on the line is

$$\mathbf{x}=\begin{bmatrix} x_0 \\ y_0 \end{bmatrix}-\begin{bmatrix} 0 \\ -a \end{bmatrix}=\begin{bmatrix} x_0 \\ y_0-a \end{bmatrix}, \tag{13}$$

so the point-line distance is

$$\mathbf{r} = (\mathbf{x} \cdot \hat{\mathbf{L}})\hat{\mathbf{L}} - \mathbf{x}$$

$$= \frac{1}{1+b^2}\left(\begin{bmatrix} x_0 \\ y_0 - a \end{bmatrix} \cdot \begin{bmatrix} 1 \\ v \end{bmatrix}\right)\begin{bmatrix} 1 \\ b \end{bmatrix} - \begin{bmatrix} x_0 \\ y_0 - a \end{bmatrix}$$

$$= \frac{y_0 - (a + bx_0)}{1 + b^2}\begin{bmatrix} b \\ -1 \end{bmatrix}. \tag{14}$$

Therefore,

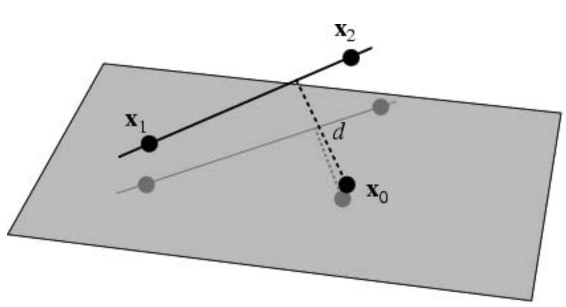
$$d = |\mathbf{r}| = \frac{|y_0 - (a + bx_0)|}{\sqrt{1 + b^2}}. \tag{15}$$

This result can also be obtained much more simply by noting that the PERPENDICULAR distance is just $\cos\theta$ times the vertical distance $|y_0 - (a + bx_1)|$. But the SLOPE b is just $\tan\theta$, so

$$\sin^2\theta + \cos^2\theta = 1 \Rightarrow \tan^2\theta + 1 = \frac{1}{\cos^2\theta}, \tag{16}$$

and

$$\cos\theta = \frac{1}{\sqrt{1 + \tan^2\theta}} = \frac{1}{\sqrt{1 + b^2}}. \tag{17}$$



The PERPENDICULAR distance is then

$$d = \frac{|y_0 - (a + bx_1)|}{\sqrt{1 + b^2}}, \tag{18}$$

the same result as before.

See also LINE, POINT, POINT-LINE DISTANCE–3-D

Point-Line Distance—3-D

Let a line in 3-D be specified by two points $\mathbf{x}_1$ and $\mathbf{x}_2$ lying on it, so a vector along the line is given by

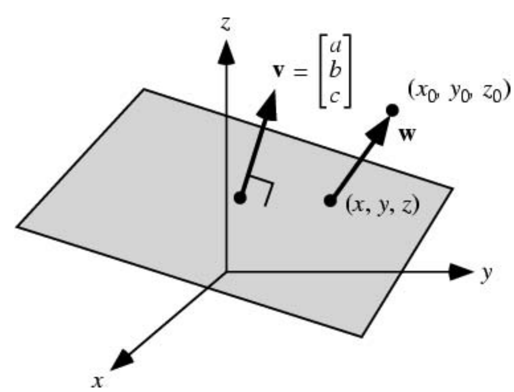
$$\mathbf{v} = \begin{bmatrix} x_1 + (x_2 - x_1)t \\ y_1 + (y_2 - y_1)t \\ z_1 + (z_2 - z_1)t \end{bmatrix}. \tag{1}$$

The distance between a point on the line with parameter t and a point (x_0, y_0, z_0) is therefore

$$r^2 = [x_1 - x_0 + (x_2 - x_1)t]^2 + [y_1 - y_0 + (y_2 - y_1)t]^2 + [z_1 - z_0 + (z_2 - z_1)t]^2. \tag{2}$$

To minimize the distance, set $d(r^2)/dt = 0$ and solve for t to obtain $t = f/g$, where

$$f = (x_1 - x_0)(x_2 - x_1) + (y_1 - y_0)(y_2 - y_1) + (z_1 - z_0)(z_2 - z_1) \tag{3}$$



$$g = (x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2, \tag{4}$$

and the minimum distance can then be found by plugging t into (2) and taking the SQUARE ROOT. This can be implemented in *Mathematica* as

```
PointLineDistance[{x1_,x2_},x0_]:=Module[
   {t=-(x1-x0).#/#.#&[x2-x1]},
   Sqrt[#.#&[x1-x0+t(x2-x1)]]
  ]
```

See also LINE, POINT, POINT-LINE DISTANCE–2-D

Point-Plane Distance

Given a PLANE

$$ax + by + cz + d = 0 \tag{1}$$

and a point (x_0, y_0, z_0), the NORMAL to the PLANE is given by

$$\mathbf{v} = \begin{bmatrix} a \\ b \\ c \end{bmatrix}, \tag{2}$$

and a VECTOR from the plane to the point is given by

$$\mathbf{w} = -\begin{bmatrix} x - x_0 \\ y - y_0 \\ z - z_0 \end{bmatrix}. \tag{3}$$

Projecting $\mathbf{w}$ onto $\mathbf{v}$,

$$D = |\text{proj}_{\mathbf{v}}\ \mathbf{w}| = \frac{|\mathbf{v}\cdot\mathbf{w}|}{|\mathbf{v}|}$$

$$= \frac{|a(x-x_0)+b(y-y_0)+c(z-z_0)|}{\sqrt{a^2+b^2+c^2}}$$

$$= \frac{|ax+by+cz-ax_0-by_0-cz_0|}{\sqrt{a^2+b^2+c^2}}$$

$$= \frac{|ax_0+by_0+cz_0+d|}{\sqrt{a^2+b^2+c^2}}. \quad (4)$$

Given three points $\mathbf{x}_i$ for $i = 1, 2, 3$, compute the unit normal

$$\hat{\mathbf{n}} = \frac{(\mathbf{x}_2-\mathbf{x}_1)\times(\mathbf{x}_3-\mathbf{x}_1)}{|(\mathbf{x}_2-\mathbf{x}_1)\times(\mathbf{x}_3-\mathbf{x}_1)|}. \quad (5)$$

Then the distance from a point $\mathbf{x}_0$ to the plane containing the three points is given by

$$D_i = \hat{\mathbf{n}}\cdot(\mathbf{x}_i-\mathbf{x}_0), \quad (6)$$

where $\mathbf{x}_i$ is any of the three points. Expanding out the coordinates shows that

$$D \equiv D_1 = D_2 = D_3, \quad (7)$$

as it must since all points are in the same plane, although this is far from obvious based on the above vector equation.

See also PROJECTION THEOREM

Point-Point Distance—1-D

Given a unit LINE SEGMENT [0, 1], pick two points at random on it. Call the first point x_1 and the second point x_2. Find the distribution of distances d between points. The probability of the points being a (POSITIVE) distance d apart (i.e., without regard to ordering) is given by

$$P(d) = \frac{\int_0^1\int_0^1 \delta(d-|x_2-x_1|)\,dx_1\,dx_2}{\int_0^1\int_0^1 dx_1\,dx_2}$$

$$= (1-d)[H(1-d)-H(d-1)+H(d)-H(-d)]$$

$$= \begin{cases} 2(1-d) & \text{for } 0 \le d \le 1 \\ 0 & \text{otherwise,} \end{cases} \quad (1)$$

where δ is the DIRAC DELTA FUNCTION and H is the HEAVISIDE STEP FUNCTION. The MOMENTS are then

$$\mu'_m = \int_0^1 d^m p(d)\,dd = 2\int_0^1 d^m(1-d)\,dd$$

$$= 2\left[\frac{d^{m+1}}{m+1}-\frac{d^{m+2}}{m+2}\right]_0^1$$

$$= 2\left(\frac{1}{m+1}-\frac{1}{m+2}\right) = 2\left[\frac{(m+2)-(m+1)}{(m+1)(m+2)}\right]$$

$$= \frac{2}{(m+1)(m+2)}$$

$$= \begin{cases} \dfrac{1}{(n+1)(2n+1)} & \text{for } m = 2n \\ \dfrac{1}{(n+1)(2n+3)} & \text{for } m = 2n+1 \end{cases} \quad (2)$$

(Uspensky 1934, p. 257), giving RAW MOMENTS

$$\mu'_1 = \tfrac{1}{3} \quad (3)$$

$$\mu'_2 = \tfrac{1}{6} \quad (4)$$

$$\mu'_3 = \tfrac{1}{10} \quad (5)$$

$$\mu'_4 = \tfrac{1}{15}. \quad (6)$$

The MOMENTS can also be computed directly without explicit knowledge of the distribution

$$\mu'_1 = \frac{\int_0^1\int_0^1 |x_2-x_1|\,dx_1\,dx_2}{\int_0^1\int_0^1 dx_1\,dx_2}$$

$$= \int_0^1\int_0^1 |x_2-x_1|\,dx_1\,dx_2$$

$$= \underset{x_2-x_1>0}{\int_0^1\int_0^1} (x_2-x_1)\,dx_1\,dx_2 + \underset{x_2-x_1<0}{\int_0^1\int_0^1} (x_1-x_2)\,dx_1\,dx_2$$

$$= \int_0^1\int_{x_1}^1 (x_2-x_1)\,dx_1\,dx_2 + \int_0^1\int_{0_1}^{x_1} (x_2-x_1)\,dx_1\,dx_2$$

$$= \int_0^1 \left[\tfrac{1}{2}x_2^2 - x_1x_2\right]_{x_1}^1 dx_1 + \int_0^1 \left[x_1x_2-\tfrac{1}{2}x_2^2\right]_0^{x_1} dx_1$$

$$= \int_0^1 \left[\left(\tfrac{1}{2}-x_1\right)-\left(\tfrac{1}{2}x_1^2-x_1^2\right)\right] dx_1$$

$$+ \int_0^1 \left[\left(x_1^2-\tfrac{1}{2}x_1^2\right)-(0-0)\right] dx_1$$

$$= \int_0^1 \left(\tfrac{1}{2}-x_1+x_1^2\right) dx_1 = \left[\tfrac{1}{2}x_1-\tfrac{1}{2}x_1^2+\tfrac{1}{3}x_1^3\right]_0^1$$

$$= \left(\tfrac{1}{2}-\tfrac{1}{2}+\tfrac{1}{3}\right)-(0-0+0) = \tfrac{1}{3} \quad (7)$$

$$\mu'_2 = \int_0^1\int_0^1 (|x_2-x_1|)^2\,dx_2\,dx_1$$

$$= \int_0^1 \int_0^1 (x_2 - x_1)^2 \, dx_1 \, dx_2$$

$$= \int_0^1 \int_0^1 (x_2^2 - 2x_1x_2 + x_1^2) \, dx_1 \, dx_2$$

$$= \int_0^1 \left[\tfrac{1}{3} x_2^3 - x_1 x_2^2 + x_1^2 x_2\right]_0^1 dx_1$$

$$= \int_0^1 \left(\tfrac{1}{3} - x_1 + x_1^2\right) dx_1 = \left[\tfrac{1}{3} x_1^3 - \tfrac{1}{2} x_1^2 + \tfrac{1}{3} x_1\right]_0^1$$

$$= \tfrac{1}{3} - \tfrac{1}{2} + \tfrac{1}{3} = \tfrac{1}{6}. \quad (8)$$

The CENTRAL MOMENTS are therefore

$$\mu_2 = \mu_2' - \mu_1'^2 = \tfrac{1}{6} - \left(\tfrac{1}{3}\right)^2 = \tfrac{1}{18} \quad (9)$$

$$\mu_3 = \mu_3' - 3\mu_2'\mu_1' + 2(\mu_1')^3 = \tfrac{1}{135} \quad (10)$$

$$\mu_4 = \mu_4' - 4\mu_3'\mu_1' + 6\mu_2'(\mu_1')^2 - 3(\mu_1')^4 = \tfrac{1}{135}, \quad (11)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \mu_1' = \tfrac{1}{3} \quad (12)$$

$$\sigma^2 = \mu_2 = \tfrac{1}{18} \quad (13)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = \tfrac{2}{5}\sqrt{2} \quad (14)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = -\tfrac{3}{5}. \quad (15)$$

The probability distribution of the distance between two points randomly picked on a LINE SEGMENT is germane to the problem of determining the access time of computer hard drives. In fact, the average access time for a hard drive is precisely the time required to seek across 1/3 of the tracks (Benedict 1995).

Point-Point Distance—2-D

Given two points in the PLANE, find the curve which minimizes the distance between them. The LINE ELEMENT is given by

$$ds = \sqrt{dx^2 + dy^2}, \quad (1)$$

so the ARC LENGTH between the points x_1 and x_2 is

$$L = \int ds = \int_{x_1}^{x_2} \sqrt{1 + y'^2} \, dx, \quad (2)$$

where $y' \equiv dy/dx$ and the quantity we are minimizing is

$$f = \sqrt{1 + y'^2}. \quad (3)$$

Finding the derivatives gives

$$\frac{\partial f}{\partial y} = 0 \quad (4)$$

$$\frac{d}{dx}\frac{\partial f}{\partial y'} = \frac{d}{dx}\left[(1 + y'^2)^{-1/2} y'\right], \quad (5)$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATION becomes

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\frac{\partial f}{\partial y'} = \frac{d}{dx}\left(\frac{y'}{\sqrt{1 + y'^2}}\right) = 0. \quad (6)$$

Integrating and rearranging,

$$\frac{y'}{\sqrt{1 + y'^2}} = c \quad (7)$$

$$y'^2 = c^2(1 + y'^2) \quad (8)$$

$$y'^2(1 - c^2) = c^2 \quad (9)$$

$$y' = \frac{c}{\sqrt{1 - c^2}} \equiv a. \quad (10)$$

The solution is therefore

$$y = ax + b, \quad (11)$$

which is a straight LINE. Now verify that the ARC LENGTH is indeed the straight-line distance between the points. a and b are determined from

$$y_1 = ax_1 + b. \quad (12)$$

$$y_2 = ax_2 + b. \quad (13)$$

Writing (12) and (13) as a MATRIX EQUATION gives

$$\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} x_1 & 1 \\ x_2 & 1 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} \quad (14)$$

$$\begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} x_1 & 1 \\ x_2 & 1 \end{bmatrix}^{-1} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$

$$= \frac{1}{x_1 - x_2} \begin{bmatrix} 1 & -1 \\ -x_2 & x_1 \end{bmatrix}^{-1} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \quad (15)$$

so

$$a = \frac{y_1 - y_2}{x_1 - x_2} = \frac{y_2 - y_1}{x_2 - x_1} \quad (16)$$

$$b = \frac{x_1 y_2 - x_2 y_1}{x_1 - x_2} \tag{17}$$

$$L = \int_{x_1}^{x_2} \sqrt{1+y'^2}\, dy = (x_2 - x_1)\sqrt{1+a^2}$$

$$= (x_2 - x_1)\sqrt{1+\left(\frac{y_2 - y_1}{x_2 - x_1}\right)^2}$$

$$= \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}, \tag{18}$$

as expected.

The shortest distance between two points on a SPHERE is the so-called GREAT CIRCLE distance.

See also CALCULUS OF VARIATIONS, CIRCLE TRIANGLE PICKING, GREAT CIRCLE, POINT-POINT DISTANCE–1-D, POINT-POINT DISTANCE–3-D, POINT-QUADRATIC DISTANCE, SPHERE POINT PICKING

References

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 930–31, 1985.

Point-Point Distance—3-D

The LINE ELEMENT is

$$ds = \sqrt{dx^2 + dy^2 + dz^2}, \tag{1}$$

so the ARC LENGTH between the points x_1 and x_2 is

$$L = \int ds = \int_{x_1}^{x_2} \sqrt{1+y'^2+z'^2}\, dx \tag{2}$$

and the quantity we are minimizing is

$$f = \sqrt{1+y'^2+z'^2}. \tag{3}$$

Finding the derivatives gives

$$\frac{\partial f}{\partial y} = 0 \tag{4}$$

$$\frac{\partial f}{\partial z} = 0 \tag{5}$$

and

$$\frac{\partial f}{\partial y'} = \frac{y'}{\sqrt{1+y'^2+z'^2}} \tag{6}$$

$$\frac{\partial f}{\partial z'} = \frac{z'}{\sqrt{1+y'^2+z'^2}}, \tag{7}$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATIONS become

$$\frac{d}{dx}\left(\frac{y'}{\sqrt{1+y'^2+z'^2}}\right) = 0 \tag{8}$$

$$\frac{d}{dx}\left(\frac{z'}{\sqrt{1+y'^2+z'^2}}\right) = 0. \tag{9}$$

These give

$$\frac{y'}{\sqrt{1+y'^2+z'^2}} = c_1 \tag{10}$$

$$\frac{z'}{\sqrt{1+y'^2+z'^2}} = c_2. \tag{11}$$

Taking the ratio,

$$z' = \frac{c_2}{c_1} y' \tag{12}$$

$$\frac{y'}{\sqrt{1+y'^2+\left(\frac{c_2}{c_1}\right)^2 y'^2}} = c_1 \tag{13}$$

$$y'^2 = c_1^2\left[1+y'^2+\left(\frac{c_2}{c_1}\right)^2 y'^2\right] = c_1^2 + y'^2(c_1^2+c_2^2), \tag{14}$$

which gives

$$y'^2 = \frac{c_1^2}{1-c_1^2-c_2^2} \equiv a_1^2 \tag{15}$$

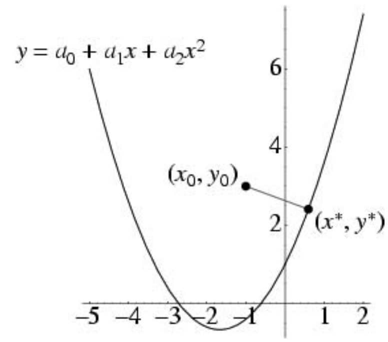
$$z'^2 = \left(\frac{c_2}{c_1}\right)^2 y'^2 = \frac{c_2^2}{1-c_1^2-c_2^2} \equiv b_1^2. \tag{16}$$

Therefore, $y' = a_1$ and $z' = b_1$, so the solution is

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} x \\ a_1 x + a_0 \\ b_1 x + b_0 \end{bmatrix}, \tag{17}$$

which is the parametric representation of a straight line with parameter $x \in [x_1, x_2]$. Verifying the ARC LENGTH gives

$$L = \sqrt{1+a_1^2+b_1^2}(x_2 - x_1) \tag{18}$$



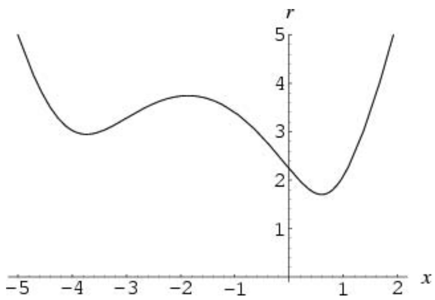
where

$$\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} x_1 & 1 \\ x_2 & 1 \end{bmatrix} \begin{bmatrix} a_1 \\ a_0 \end{bmatrix} \tag{19}$$

$$\begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} x_1 & 1 \\ x_2 & 1 \end{bmatrix} \begin{bmatrix} b_1 \\ b_0 \end{bmatrix}. \tag{20}$$

See also POINT-POINT DISTANCE–1-D, POINT-POINT DISTANCE–2-D, POINT-QUADRATIC DISTANCE

Point-Quadratic Distance



To find the minimum distance between a point in the plane (x_0, y_0) and a quadratic PLANE CURVE

$$y = a_0 + a_1 x + a_2 x^2, \tag{1}$$

note that the square of the distance is

$$\begin{aligned} r^2 &= (x - x_0)^2 + (y - y_0)^2 \\ &= (x - x_0)^2 + (a_0 + a_1 x + a_2 x^2 - y_0)^2. \end{aligned} \tag{2}$$

Minimizing the distance squared is equivalent to minimizing the distance (since r^2 and $|r|$ have minima at the same point), so take

$$\begin{aligned} \frac{\partial(r^2)}{\partial x} &= 2(x - x_0) + 2(a_0 + a_1 x + a_2 x^2 - y_0)(a_1 + 2a_2 x) \\ &= 0 \end{aligned} \tag{3}$$

$$\begin{aligned} x - x_0 + a_0 a_1 + a_1^2 + a_1 a_2 x^2 - a_1 y_0 + 2a_0 a_2 x \\ + 2a_1 a_2 x^2 + 2a_2^2 x^3 - 2a_2 y_0 x = 0 \end{aligned} \tag{4}$$

$$\begin{aligned} 2a_2^2 x^3 + 3a_1 a_2 x^2 + (a_1^2 + 2a_0 a_2 - 2a_2 y_0 + 1)x \\ + (a_0 a_1 - a_1 y_0 - x_0) = 0. \end{aligned} \tag{5}$$

Minimizing the distance to find the closest point (x^*, y^*) therefore requires solution of a CUBIC EQUATION.

Points Problem

SHARING PROBLEM

Point-Set Topology

The low-level language of TOPOLOGY, which is not really considered a separate "branch" of TOPOLOGY. Point-set topology, also called set-theoretic topology or general topology, is the study of the general abstract nature of continuity or "closeness" on SPACES. Basic point-set topological notions are ones like CONTINUITY, DIMENSION, COMPACTNESS, and CONNECTEDNESS. The INTERMEDIATE VALUE THEOREM (which states that if a path in the real line connects two numbers, then it passes over every point between the two) is a basic topological result. Others are that EUCLIDEAN n-space is HOMEOMORPHIC to EUCLIDEAN m-space IFF $m = n$, and that REAL valued functions achieve maxima and minima on COMPACT SETS.

Foundational point-set topological questions are ones like "when can a topology on a space be derived from a metric?" Point-set topology deals with differing notions of continuity and compares them, as well as dealing with their properties. Point-set topology is also the ground-level of inquiry into the geometrical properties of spaces and continuous functions between them, and in that sense, it is the foundation on which the remainder of topology (ALGEBRAIC, DIFFERENTIAL, and LOW-DIMENSIONAL) stands.

See also ALGEBRAIC TOPOLOGY, DIFFERENTIAL TOPOLOGY, LOW-DIMENSIONAL TOPOLOGY, TOPOLOGY

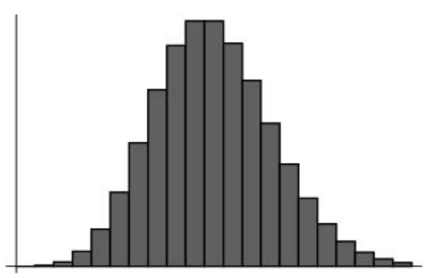
Poised

NEARLY-POISED, WELL-POISED

Poisson Bracket

Let F and G be infinitely differentiable functions of x and p. Then the Poisson bracket is defined by

$$(F,\ G)=\sum_{v=1}^{n}\left(\frac{\partial F}{\partial p_v}\frac{\partial G}{\partial x_v}-\frac{\partial G}{\partial p_v}\frac{\partial F}{\partial x_v}\right).$$



If F and G are functions of x and p only, then the LAGRANGE BRACKET $[F,\ G]$ collapses the Poisson bracket $(F,\ G)$.

See also LAGRANGE BRACKET, LIE BRACKET

Poisson Distribution

Given a POISSON PROCESS, the probability of k changes occurring in a given interval is given by the limit of the BINOMIAL DISTRIBUTION

$$P_B(k)=\frac{n!}{k!(n-k)!}\left(\frac{v}{n}\right)^k\left(1-\frac{v}{n}\right)^{n-k}. \tag{1}$$

As the number of trials becomes very large, (1) approaches the distribution

$$\begin{aligned}P(k)&=\lim_{n\to\infty}P_B(k)\\&=\lim_{n\to\infty}\frac{n(n-1)\cdots(n-k+1)}{n^k}\frac{v^k}{k!}\\&\quad\times\left(1-\frac{v}{n}\right)^n\left(1-\frac{v}{n}\right)^{-k}\\&=1\cdot\frac{v^k}{k!}\cdot e^{-v}\cdot 1=\frac{v^ke^{-v}}{k!},\end{aligned} \tag{2}$$

which is called the Poisson distribution (Papoulis 1984, pp. 101 and 554; Pfeiffer and Schum 1973, p. 200).

The Poisson distribution is normalized so that the sum of probabilities equals 1, since

$$\sum_{k=0}^{\infty}P(k)=e^{-v}\sum_{k=0}^{\infty}\frac{v^k}{k!}=e^{-v}e^{v}=1. \tag{3}$$

The ratio of probabilities is given by

$$\frac{P(k=i+1)}{P(k=i)}=\frac{\dfrac{v^{i+1}e^{-v}}{(i+1)!}}{\dfrac{i!}{e^{-v}v^i}}=\frac{v}{i+1}. \tag{4}$$

The MOMENT-GENERATING FUNCTION of the Poisson distribution is given by

$$\begin{aligned}M(t)&=\sum_{k=0}^{\infty}e^{tk}\frac{v^ke^{-v}}{k!}=e^{-v}\sum_{k=0}^{\infty}\frac{(ve^t)^k}{k!}\\&=e^{-v}e^{ve^t}=e^{v(e^t-1)}\end{aligned} \tag{5}$$

$$M'(t)=ve^te^{v(e^t-1)} \tag{6}$$

$$M''(t)=(ve^t)^2e^{v(e^t-1)}+ve^te^{v(e^t-1)} \tag{7}$$

$$R(t)\equiv\ln M(t)=v(e^t-1) \tag{8}$$

$$R'(t)=ve^t \tag{9}$$

$$R''(t)=ve^t, \tag{10}$$

so

$$\mu=R'(0)=v \tag{11}$$

$$\sigma^2=R''(0)=v \tag{12}$$

(Papoulis 1984, p. 554).

The RAW MOMENTS can also be computed directly by summation, which yields an unexpected connection with STIRLING NUMBERS OF THE SECOND KIND,

$$\sum_{k=0}^{\infty}\frac{e^{-x}x^k}{k!}k^n=\sum_{k=1}^{n}x^kS(n,\ k), \tag{13}$$

so

$$\mu'_2 = \nu(1+\nu) \tag{14}$$

$$\mu'_3 = \nu\left(1+3\nu+\nu^2\right) \tag{15}$$

$$\mu'_4 = \nu\left(1+7\nu+6\nu^2+\nu^3\right). \tag{16}$$

The CENTRAL MOMENTS can then be computed as

$$\mu_2 = \nu \tag{17}$$

$$\mu_3 = \nu \tag{18}$$

$$\mu_4 = \nu(1+3\nu), \tag{19}$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \nu \tag{20}$$

$$\sigma^2 = \nu \tag{21}$$

$$\gamma_1 \equiv \frac{\mu_3}{\sigma^3} = \frac{\nu}{\nu^{3/2}} = \nu^{-1/2} \tag{22}$$

$$\gamma_2 \equiv \frac{\mu_4}{\sigma^4} - 3 = \frac{\nu(1+3\nu)}{\nu} - 3$$

$$= \frac{\nu + 3\nu^2 - 3\nu^2}{\nu^2} = \nu^{-1}. \tag{23}$$

The CHARACTERISTIC FUNCTION for the Poisson distribution is

$$\phi(t) = e^{\nu\left(e^{it}-1\right)} \tag{24}$$

(Papoulis 1984, pp. 154 and 554), and the CUMULANT-GENERATING FUNCTION is

$$K(h) = \nu\left(e^h - 1\right) = \nu\left(h + \frac{1}{2!}h^2 + \frac{1}{3!}h^3 + \ldots\right), \tag{25}$$

so

$$\kappa_r = \nu. \tag{26}$$

The Poisson distribution can also be expressed in terms of

$$\lambda \equiv \frac{\nu}{x}, \tag{27}$$

the rate of changes, so that

$$P(k) = \frac{(\lambda x)^k e^{-\lambda x}}{k!}. \tag{28}$$

The MOMENT-GENERATING FUNCTION of a Poisson distribution in two variables is given by

$$M(t) = e^{(\nu_1+\nu_2)(e^t-1)}. \tag{29}$$

If the independent variables $x_1, x_2, \ldots, x_N$ have Poisson distributions with parameters $\mu_1, \mu_2, \ldots, \mu_N$, then

$$X = \sum_{j=1}^{N} x_j \tag{30}$$

has a Poisson distribution with parameter

$$\mu = \sum_{j=1}^{N} \mu_j. \tag{31}$$

This can be seen since the CUMULANT-GENERATING FUNCTION is

$$K_j(h) = \mu_j\left(e^h - 1\right), \tag{32}$$

$$K \equiv \sum_j K_j(h) = \left(e^h - 1\right)\sum_j \mu_j = \mu\left(e^h - 1\right). \tag{33}$$

A generalization of the Poisson distribution has been used by Saslaw (1989) to model the observed clustering of galaxies in the universe. The form of this distribution is given by

$$f_b(N) = \frac{\bar{N}(1-b)}{N!}\left[\bar{N}(1-b)+Nb\right]^{N-1} e^{\bar{N}(1-b)-Nb}, \tag{34}$$

where N is the number of galaxies in a volume V, $\bar{N} = \bar{n}V$, $\bar{n}$ is the average density of galaxies, and $b = -W/(2K) \approx 0.70 \pm 0.05$, with $0 \leq b < 1$ is the ratio of gravitational energy to the kinetic energy of peculiar motions, Letting $b = 0$ gives

$$f_0(N) = \frac{e^{-\bar{N}}\bar{N}^N}{N!}, \tag{35}$$

which is indeed a Poisson distribution with $\nu = \bar{N}$. Similarly, letting $b = 1$ gives $f_1(N) = 0$.

Poisson Integral

There are at least two integrals called the Poisson integral. The first is also known as BESSEL'S SECOND INTEGRAL,

$$J_n(z) = \frac{\left(\frac{1}{2}\right)^n}{\Gamma\left(n+\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)} \int_0^\pi \cos(z\cos\theta)\sin^{2n}\theta\,d\theta,$$

where $J_n(z)$ is a BESSEL FUNCTION OF THE FIRST KIND and $\Gamma(x)$ is a GAMMA FUNCTION. It can be derived from SONINE'S INTEGRAL. With $n=0$, the integral becomes PARSEVAL'S INTEGRAL.

In complex analysis, let $u : U \to \mathbb{R}$ be a HARMONIC FUNCTION on a NEIGHBORHOOD of the CLOSED DISK $\bar{D}(0,\ 1)$, then for any point z_0 in the OPEN DISK $D(0,\ 1)$,

$$u(z_0) = \frac{1}{2\pi}\int_0^{2\pi} u\left(e^{i\psi}\right)\frac{1-|z_0|^2}{|z_0 - e^{i\psi}|^2}\,d\psi.$$

In polar coordinates on $\bar{D}(0,\ R)$,

$$u(z_0) = \frac{1}{2\pi}\int_0^{2\pi} K(r,\ \theta)\phi\left(z_0 + re^{i\theta}\right)d\theta, \tag{1}$$

where $R = |z_0|$ and $K(r,\ \theta)$ is the POISSON KERNEL. For a CIRCLE,

$$u(x,\ y) = \frac{1}{2\pi}\int_0^{2\pi} u(a\cos\phi,\ a\sin\phi) \times \frac{a^2 - R^2}{a^2 + R^2 - 2ar\cos(\theta-\phi)}\,d\phi. \tag{2}$$

For a SPHERE,

$$u(x,\ y,\ z) = \frac{1}{4\pi a}\int\int_S u\,\frac{a^2-R^2}{\left(a^2+R^2-2aR\cos\theta\right)^{3/2}}\,dS, \tag{3}$$

where

$$\cos\theta \equiv \mathbf{x}\cdot\xi. \tag{4}$$

See also BESSEL FUNCTION OF THE FIRST KIND, CIRCLE, HARMONIC FUNCTION, PARSEVAL'S INTEGRAL, POISSON KERNEL, SONINE'S INTEGRAL, SPHERE

Poisson Integral Representation

$$j_n(z) = \frac{z^n}{2^{n+1}n!}\int_0^\pi \cos(z\cos\theta)\sin^{2n+1}\theta\,d\theta,$$

where $j_n(z)$ is a SPHERICAL BESSEL FUNCTION OF THE FIRST KIND.

Poisson Kernel

The KERNEL in the POISSON INTEGRAL, given by

$$K(\psi) = \frac{1}{2\pi}\frac{1-|z_0|^2}{|z_0 - e^{i\psi}|^2} \tag{1}$$

for the open UNIT DISK $D(0,\ 1)$. Writing $z_0 = re^{i\theta}$ and taking $D(0,\ R)$ gives

$$\begin{aligned}
K(r,\ \theta) &\equiv \frac{1}{2\pi}\Re\left[\frac{R+re^{i\theta}}{R-re^{i\theta}}\right] \\
&= \frac{1}{2\pi}\Re\left[\frac{(R+re^{i\theta})(R-re^{-i\theta})}{(R-re^{i\theta})(R-re^{-i\theta})}\right] \\
&= \frac{1}{2\pi}\Re\left[\frac{R^2 - rR(e^{i\theta}-e^{-i\theta}) - r^2}{R^2 - rR(e^{i\theta}+e^{-i\theta}) + r^2}\right] \\
&= \frac{1}{2\pi}\Re\left[\frac{R^2 + 2ir\,R\sin\theta - r^2}{R^2 - 2Rr\cos\theta + r^2}\right] \\
&= \frac{1}{2\pi}\frac{R^2 - r^2}{R^2 - 2Rr\cos\theta + r^2}
\end{aligned} \tag{2}$$

(Krantz 1999, p. 93).

In 3-D,

$$u(\mathbf{y}) = \frac{R(R^2-a^2)}{4\pi}\int_0^{2\pi}\int_0^\pi \frac{f(\theta,\ \phi)\sin\theta\,d\theta\,d\phi}{\left(R^2+a^2-2aR\cos\gamma\right)^{3/2}}, \tag{3}$$

where $a = |\mathbf{y}|$ and

$$\cos\gamma = \mathbf{y}\cdot\begin{bmatrix} R\cos\theta\sin\phi \\ R\sin\theta\sin\phi \\ R\cos\phi \end{bmatrix}. \tag{4}$$

The Poisson kernel for the n-BALL is

$$P(\mathbf{x},\ \mathbf{z}) = \frac{1}{2-n}(D_\mathbf{n}\mathbf{v})(\mathbf{z}), \tag{5}$$

where $D_\mathbf{n}$ is the outward normal derivative at point $\mathbf{z}$ on a unit n-sphere and

$$\mathbf{v}(\mathbf{z}) = |\mathbf{z}-\mathbf{x}|^{2-n} - |\mathbf{x}|^{2-n}\left|\frac{\mathbf{x}}{|\mathbf{x}|^2}\right|^{2-n}. \tag{6}$$

Let u be harmonic on a neighborhood of the closed UNIT DISK $\bar{D}(0,\ 1)$, then the reproducing property of the Poisson kernal states that for $z \in D(0,\ 1)$,

$$u(z)=\frac{1}{2\pi}\int_0^{2\pi} u(e^{i\psi})\frac{1-|z|^2}{|z-e^{i\psi}|^2}\,d\psi \qquad (7)$$

(Krantz 1999, p. 94).

Poisson Manifold

A smooth MANIFOLD with a POISSON BRACKET defined on its FUNCTION SPACE.

Poisson Process

A Poisson is a process satisfying the following properties.

1. The numbers of changes in nonoverlapping intervals are independent for all intervals.
2. The probability of exactly one change in a sufficiently small interval $h\equiv 1/n$ is $P=vh\equiv v/n$, where v is the probability of one change and n is the number of TRIALS.
3. The probability of two or more changes in a sufficiently small interval h is essentially 0.

In the limit of the number of trials becoming large, the resulting distribution is called a POISSON DISTRIBUTION.

See also POISSON DISTRIBUTION

Poisson Sum Formula

A special case of the general result

$$\sum_{n=-\infty}^{\infty} f(x+n)=\sum_{k=-\infty}^{\infty} e^{2\pi ikx}\int_{-\infty}^{\infty} f(x')e^{-2\pi ikx'}\,dx' \qquad (1)$$

with $x=0$, yielding

$$\sum_{n=-\infty}^{\infty} f(n)=\sum_{k=-\infty}^{\infty}\int_{-\infty}^{\infty} f(x')e^{-2\pi ikx'}\,dx'. \qquad (2)$$

Given f a nonnegative, continuous, decreasing, and Riemann integrable function of $[0,\ \infty)$, define

$$\psi(x)=\sqrt{\frac{2}{\pi}}\int_0^{\infty}\phi(t)\cos(xt)\,dt. \qquad (3)$$

Then

$$\sqrt{\alpha}\left[\tfrac{1}{2}f(0)+\sum_{n=1}^{\infty} f(n\alpha)\right]=\sqrt{\beta}\left[\tfrac{1}{2}g(0)+\sum_{n=1}^{\infty} g(n\beta)\right] \qquad (4)$$

whenever $\alpha\beta=2\pi$, from which it follows that

$$\sqrt{\alpha}\left[\tfrac{1}{2}+\sum_{n=1}^{\infty} e^{-\alpha^2n^2/2}\right]=\sqrt{\beta}\left[\tfrac{1}{2}+\sum_{n=1}^{\infty} e^{-\beta^2n^2/2}\right] \qquad (5)$$

(Apostol 1974, Borwein 1987).

Poisson Theorem

Poisson's theorem give the estimate

$$\frac{n!}{k!(n-k)!}\,p^kq^{n-k}\sim e^{-np}\,\frac{(np)^k}{k!}$$

for the probability of an event occurring k times in n trials with $n\gg 1$, $p\ll 1$, and $np\approx npq\gg 1$.

See also POISSON DISTRIBUTION

References

Papoulis, A. *Probability, Random Variables, and Stochastic Processes, 2nd ed.* New York: McGraw-Hill, p. 71, 1984.

Poisson Trials

A number s of TRIALS in which the probability of success p_i varies from trial to trial. Let x be the number of successes, then

$$\mathrm{var}(x)=spq-s\sigma_p^2, \qquad (1)$$

where σ_p^2 is the VARIANCE of p_i and $q\equiv(1-p)$. Uspensky has shown that

$$P(s,\ x)=\beta\,\frac{m^xe^{-m}}{x!}, \qquad (2)$$

where

$$\beta=[1-\theta g(x)]e^{h(x)} \qquad (3)$$

$$g(x) = \frac{(s-x)m^3}{3(s-m)^3} + \frac{x^3}{2s(s-x)} \quad (4)$$

$$h(x) = \frac{mx}{s} - \frac{m^2}{2s^2}(s-x) - \frac{x(x-1)}{2s}$$

$$= p\left[\frac{x}{2}\left(1+\frac{1}{m}\right) - \frac{(x-m)^2}{2m}\right] \quad (5)$$

and $\theta \in (0, 1)$. The probability that the number of successes is at least x is given by

$$Q_m(x) = \sum_{r=x}^{\infty} \frac{m^r e^{-m}}{r!}. \quad (6)$$

Uspensky gives the true probability that there are at least x successes in s trials as

$$P_{ms}(x) = Q_m(x) + \Delta, \quad (7)$$

where

$$|\Delta| < \begin{cases} (e^\chi - 1)Q_m(x+1) & \text{for } Q_m(x+1) \geq \frac{1}{2} \\ (e^\chi - 1)[1 - Q_m(x+1)] & \text{for } Q_m(x+1) \leq \frac{1}{2} \end{cases} \quad (8)$$

$$\chi = \frac{m + \frac{1}{4} + \frac{m^3}{s}}{2(s-m)}. \quad (9)$$

Poisson-Charlier Polynomial

The Poisson-Charlier polynomials $c_k(x;\ a)$ form a SHEFFER SEQUENCE with

$$g(t) = e^{a(e^t-1)} \quad (1)$$

$$f(t) = a(e^t - 1), \quad (2)$$

giving the GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{c_k(x;\ a)}{k!} t^k = e^{-t}\left(\frac{a+t}{a}\right)^x. \quad (3)$$

The Sheffer identity is

$$c_n(x+y;\ a) = \sum_{k=0}^{n} \binom{n}{k} a^{k-n} c_k(y;\ a)(x)_{n-k}, \quad (4)$$

where $(x)_n$ is a FALLING FACTORIAL (Roman 1984, p. 121). The polynomials satisfy the RECURRENCE RELATION

$$c_{n+1}(x;\ a) = a^{-1}xc_n(x-1;\ a) - c_n(x;\ a). \quad (5)$$

These polynomials belong to the distribution $d\alpha(x)$ where $\alpha(x)$ is a STEP FUNCTION with JUMP

$$j(x) = e^{-a}a^x(x!)^{-1} \quad (6)$$

at $x = 0, 1, \ldots$ for $a > 0$. They are given by the formulas

$$c_n(x;\ a) = \sum_{\nu=0}^{n} (-1)^{n-\nu} \binom{n}{\nu} \nu! a^{-\nu} \binom{x}{\nu} \quad (7)$$

$$= \sum_{k=0}^{n} \binom{n}{k} (-1)^{n-k} a^{-k} (x)_k \quad (8)$$

$$= a^n(-1)^n [j(x)]^{-1} \Delta^n j(x-n) \quad (9)$$

$$= a^{-n} n! L_n^{x-n}(a) \quad (10)$$

$$= \sum_{j=0}^{n} x^j \sum_{k=0}^{n} \binom{n}{k} (-1)^{n-k} a^{-k} s(k, j) \quad (11)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, $(x)_n$ is a FALLING FACTORIAL, $L_n^k(x)$ is an associated LAGUERRE POLYNOMIAL, $s(n, m)$ is a STIRLING NUMBER OF THE FIRST KIND, and

$$\Delta f(x) = f(x+1) - f(x) \quad (12)$$

$$\Delta^n f(x) = \Delta\left[\Delta^{n-1} f(x)\right]$$
$$= f(x+n) - \binom{n}{1} f(x+n-1) + \ldots + (-1)^n f(x). \quad (13)$$

They are normalized so that

$$\sum_{k=0}^{\infty} j(k) c_n(k;\ a) c_m(k;\ a) = a^{-n} n! \delta_{nm}, \quad (14)$$

where δ_{mn} is the DELTA FUNCTION.

The first few polynomials are

$$c_0(x;\ a) = 1$$
$$c_1(x;\ a) = -\frac{a - x}{a}$$
$$c_2(x;\ a) = \frac{a^2 - x - 2ax + x^2}{a^2}$$
$$c_3(x;\ a) = -\frac{a^3 - 2x - 3ax - 3a^2x + 3x^2 + 3ax^2 - x^3}{a^3}.$$

Poke Move

The REIDEMEISTER MOVE of type II.

See also KNOT MOVE, REIDEMEISTER MOVES

Poker

Poker is a CARD game played with a normal deck of 52 CARDS. Sometimes, additional cards called "jokers" are also used. In straight or draw poker, each player is normally dealt a hand of five cards. Depending on the variant, players then discard and redraw CARDS, trying to improve their hands. Bets are placed at each discard step. The number of possible distinct five-card hands is

$$N = \binom{52}{5} = 2,598,960,$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

There are special names for specific types of hands. A royal flush is an ace, king, queen, jack, and 10, all of one suit. A straight flush is five consecutive cards all of the same suit (but not a royal flush), where an ace may count as either high or low. A full house is three-of-a-kind and a pair. A flush is five cards of the same suit (but not a royal flush or straight flush). A straight is five consecutive cards (but not a royal flush or straight flush), where an ace may again count as either high or low.

The probabilities of being dealt five-card poker hands of a given type (before discarding and with no jokers) on the initial deal are given below (Packel 1981). As usual, for a hand with probability P, the ODDS against being dealt it are $(1/r) - 1 : 1$.

Hand	Exact Probability	Probability	ODDS
royal flush	$\frac{4}{N} = \frac{1}{649,740}$	1.54×10^{-6}	649,739.0:1
straight flush	$\frac{4(10) - 4}{N} = \frac{3}{216,580}$	1.39×10^{-5}	72,192.3:1
four of a kind	$\frac{13(48)}{N} = \frac{1}{4,165}$	2.40×10^{-4}	4,164.0:1
full house	$\frac{13\binom{4}{3}12\binom{4}{2}}{N} = \frac{6}{4,165}$	1.44×10^{-3}	693.2:1
flush	$\frac{4\binom{13}{5} - 36 - 4}{N} = \frac{1,277}{649,740}$	1.97×10^{-3}	507.8:1

straight	$\frac{10(4^5)-36-4}{N}=\frac{5}{1,274}$	3.92×10^{-3}	253.8:1
three of a kind	$\frac{13\binom{4}{3}\frac{(48)(44)}{2!}}{N}=\frac{88}{4,165}$	0.0211	46.3:1
two pair	$\frac{\frac{13\binom{4}{2}12\binom{4}{2}}{2!}44}{N}=\frac{198}{4,165}$	0.0475	20.0:1
one pair	$\frac{13\binom{4}{2}\frac{(48)(44)(40)}{3!}}{N}=\frac{352}{833}$	0.423	1.366:1

Gadbois (1996) gives probabilities for hands if two jokers are included, and points out that it is *impossible* to rank hands in any single way which is consistent with the relative frequency of the hands.

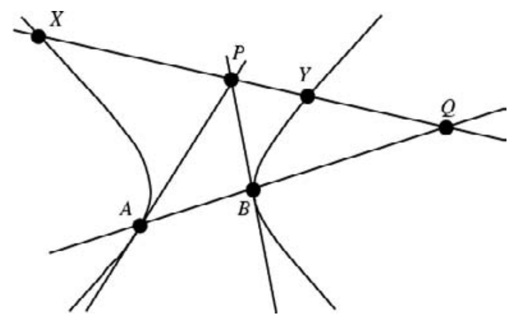
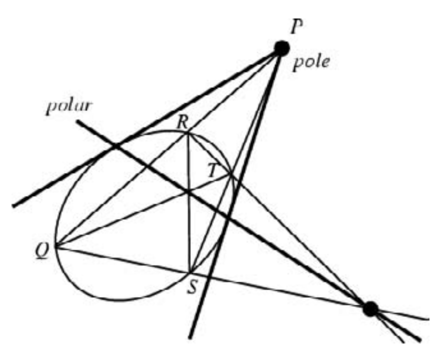
Polar



If two points A and A' are inverse (sometimes called conjugate) with respect to a circle (the inversion circle), then the straight line through A' which is perpendicular to the line of the points AA' is called the polar of A with respect to the circle, and A is called the pole of the polar.



An incidence-preserving transformation in which points and lines are transformed into their poles and polars is called reciprocation (a.k.a. constructing the dual).

The concept of poles and polars can also be generalized to arbitrary conic sections. If two tangents to a conic section at points A and B meet at P, then P is called the pole of the line AB with respect to the conic and AB is said to be the polar of the point P with respect to the conic (Wells 1991).

In the above figure, let a line through the polar P meet a conic section at point X and Y, and let the line XY intersect the polar line AB and Q. Then $\{XPYQ\}$ form a harmonic range (Wells 1991).

In the above figure, let two lines through the polar P meet a conic at points P and Q and S and T. Then QT and RS are concurrent on the polar (Wells 1991).

The concept can be generalized even further to an arbitrary algebraic curve so that every point has a polar with respect to the curve and every line has a pole (Wells 1991).

Polar Angle

The counterclockwise ANGLE from the X-AXIS at which a point lies.

See also POLAR COORDINATES

Polar Circle

Given a TRIANGLE, the polar circle has center at the ORTHOCENTER H. Call H_i the FEET of the ALTITUDE. Then the RADIUS is

$$r^2 = \overline{HA_1} \cdot \overline{HH_1} = \overline{HA_2} \cdot \overline{HH_2} = \overline{HA_2} \cdot \overline{HH_2} \tag{1}$$

$$= -4R^2 \cos\alpha_1 \cos\alpha_2 \cos\alpha_3 \tag{2}$$

$$= \tfrac{1}{2}(a_1^2 + a_2^2 + a_3^2) - 4R^2, \tag{3}$$

where R is the CIRCUMRADIUS, α_i the VERTEX angles, and a_i the corresponding side lengths.

A TRIANGLE is self-conjugate with respect to its polar circle. Also, the RADICAL AXIS of any two polar circles is the ALTITUDE from the third VERTEX. Any two polar circles of an ORTHOCENTRIC SYSTEM are orthogonal. The polar circles of the triangles of a COMPLETE QUADRILATERAL constitute a COAXAL SYSTEM conjugate to that of the circles on the diagonals.

Polar Coordinates

The polar coordinates r (the radial coordinate) and θ (the angular coordinate) are defined in terms of CARTESIAN COORDINATES by

$$x = r\cos\theta \tag{1}$$

$$y = r\sin\theta, \tag{2}$$

where r is the radial distance from the ORIGIN, and θ is the counterclockwise angle from the X-AXIS. In terms of x and y,

$$r = \sqrt{x^2 + y^2} \tag{3}$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right). \tag{4}$$

The ARC LENGTH of a polar curve given by $r = r(\theta)$ is

$$s = \int_{\theta_1}^{\theta_2} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2}\, d\theta. \tag{5}$$

The LINE ELEMENT is given by

$$ds^2 = r^2\, d\theta^2, \tag{6}$$

and the AREA element by

$$dA = r\, dr\, d\theta. \tag{7}$$

The AREA enclosed by a polar curve $r = r(\theta)$ is

$$A = \tfrac{1}{2}\int_{\theta_1}^{\theta_2} r^2\, d\theta. \tag{8}$$

The SLOPE of a polar function $r = r(\theta)$ at the point (r, θ) is given by

$$m = \frac{r + \tan\theta \dfrac{dr}{d\theta}}{-r\tan\theta + \dfrac{dr}{d\theta}}. \tag{9}$$

The ANGLE between the tangent and radial line at the point (r, θ) is

$$\psi = \tan^{-1}\left(\frac{r}{\dfrac{dr}{d\theta}}\right). \tag{10}$$

A polar curve is symmetric about the X-AXIS if replacing θ by $-\theta$ in its equation produces an equivalent equation, symmetric about the Y-AXIS if replacing θ by $\pi-\theta$ in its equation produces an equivalent equation, and symmetric about the origin if replacing r by $-r$ in its equation produces an equivalent equation.

In Cartesian coordinates, the POSITION VECTOR and its derivatives are

$$\mathbf{r} = \sqrt{x^2+y^2}\,\hat{\mathbf{r}} \tag{11}$$

$$\dot{\mathbf{r}} = \dot{\hat{\mathbf{r}}}\sqrt{x^2+y^2} + \hat{\mathbf{r}}(x^2+y^2)^{-1/2}(x\dot{x}+y\dot{y}) \tag{12}$$

$$\hat{\mathbf{r}} = \frac{x\hat{\mathbf{x}} + y\hat{\mathbf{y}}}{\sqrt{x^2+y^2}} \tag{13}$$

$$\dot{\hat{\mathbf{r}}} = \frac{\dot{x}\hat{\mathbf{x}} + \dot{y}\hat{\mathbf{y}}}{\sqrt{x^2+y^2}} - \tfrac{1}{2}(x^2+y^2)^{-3/2}(2)(x\dot{x}+y\dot{y})(x\hat{\mathbf{x}}+y\hat{\mathbf{y}})$$

$$= \frac{(x\dot{y}+y\dot{x})(x\hat{\mathbf{y}}-y\hat{\mathbf{x}})}{(x^2+y^2)^{3/2}}. \tag{14}$$

In polar coordinates, the UNIT VECTORS and their derivatives are

$$\mathbf{r} \equiv \begin{bmatrix} r\cos\theta \\ r\sin\theta \end{bmatrix} \tag{15}$$

$$\hat{\mathbf{r}} \equiv \frac{\frac{d\mathbf{r}}{dr}}{\left|\frac{d\mathbf{r}}{dr}\right|} = \begin{bmatrix} \cos\theta \\ \sin\theta \end{bmatrix} \tag{16}$$

$$\hat{\boldsymbol{\theta}} \equiv \frac{\frac{d\theta}{d\theta}}{\left|\frac{d\theta}{d\theta}\right|} = \begin{bmatrix} -\sin\theta \\ \cos\theta \end{bmatrix} \tag{17}$$

$$\dot{\hat{\mathbf{r}}} = \begin{bmatrix} -\sin\theta\dot{\theta} \\ \cos\theta\dot{\theta} \end{bmatrix} = \dot{\theta}\hat{\boldsymbol{\theta}} \tag{18}$$

$$\dot{\hat{\boldsymbol{\theta}}} = \begin{bmatrix} -\cos\theta\dot{\theta} \\ \sin\theta\dot{\theta} \end{bmatrix} = -\dot{\theta}\hat{\mathbf{r}} \tag{19}$$

$$\dot{\mathbf{r}} = \begin{bmatrix} -r\sin\theta\dot{\theta} + \cos\theta\dot{r} \\ r\cos\theta\dot{\theta} + \sin\theta\dot{r} \end{bmatrix} = r\dot{\theta}\hat{\boldsymbol{\theta}} + \dot{r}\hat{\mathbf{r}} \tag{20}$$

$$\ddot{\mathbf{r}} = \dot{r}\dot{\theta}\hat{\boldsymbol{\theta}} + r\ddot{\theta}\hat{\boldsymbol{\theta}} + r\dot{\theta}\dot{\hat{\boldsymbol{\theta}}} + \ddot{r}\hat{\mathbf{r}} + \dot{r}\dot{\hat{\mathbf{r}}}$$

$$= \dot{r}\dot{\theta}\hat{\boldsymbol{\theta}} + r\ddot{\theta}\hat{\boldsymbol{\theta}} + r\dot{\theta}(-\dot{\theta}\hat{\mathbf{r}}) + \ddot{r}\hat{\mathbf{r}} + \dot{r}\dot{\theta}\hat{\boldsymbol{\theta}}$$

$$= (\ddot{r} - r\dot{\theta}^2)\hat{\mathbf{r}} + (2\dot{r}\dot{\theta} + r\ddot{\theta})\hat{\theta}$$

$$= (\ddot{r} - r\dot{\theta}^2)\hat{\mathbf{r}} + \frac{1}{r}\frac{d}{dt}\left(r^2\dot{\theta}\right)\hat{\boldsymbol{\theta}}. \tag{21}$$

Polar Representation (Complex Number)

PHASOR

Polar Representation (Measure)

A polar representation of a COMPLEX MEASURE μ is analogous to the polar representation of a COMPLEX NUMBER as $z = re^{i\theta}$, where $r = |z|$,

$$d\mu = e^{i\theta} d|\mu|. \tag{1}$$

The analog of absolute value is the TOTAL VARIATION MEASURE $|\mu|$, and θ is replaced by a MEASURABLE real-valued function θ. Or sometimes one writes h with $|h| = 1$ instead of $e^{i\theta}$.

More precisely, for any measurable set E,

$$\mu(E) = \int_E e^{i\theta}\, d|\mu|, \tag{2}$$

where the integral is the LEBESGUE INTEGRAL. It is natural to extend the definition of the Lebesgue integral to complex measures using the polar representation

$$\int f\, d\mu = \int e^{i\theta} f\, d|\mu|. \tag{3}$$

GOSSIPING

Pole

A HOLOMORPHIC FUNCTION f has a pole of order m at a point $z = z_0$ if, in the LAURENT SERIES, $a_n = 0$ for $n < -m$ and $a_m \neq 0$. Equivalently, f has a pole of order n at z_0 if n is the smallest POSITIVE INTEGER for which $(z - z_0)^n f(z)$ is holomorphic at z_0. A holomorphic function f has a pole at infinity if

$$\lim_{z \to \infty} f(z) = \infty.$$

A nonconstant polynomial $P(z)$ has a pole at infinity of order deg P, i.e., the DEGREE of P.

The basic example of a pole is $f = 1/z^n$, which has a single pole of order n at $z = 0$. A simple *Mathematica* function which finds the poles of a RATIONAL FUNCTION is given by

```
Poles[f_, z_] := Union[z /.
{ToRules[Roots[Denominator[Together[D[f, z]]]
== 0, z]]}]
```

A HOLOMORPHIC FUNCTION whose only singularities are poles is called a MEROMORPHIC FUNCTION.

Pole (Inversion)

If two points A and A' are INVERSE with respect to a CIRCLE (the INVERSION CIRCLE), then the straight line through A' which is PERPENDICULAR to the line of the points AA' is called the POLAR of the POINT A with respect to the CIRCLE, and A is called the pole of the POLAR.

An incidence-preserving transformation in which points and lines are transformed into their poles and POLARS is called a RECIPROCATION.

The concept of poles and polars can also be generalized to arbitrary CONIC SECTIONS. If two tangents to a CONIC SECTION at points A and B meet at P, then P is called the pole of the line AB with respect to the conic and AB is said to be the POLAR of the point P with respect to the conic (Wells 1991). Let a line through P meet a conic at points X and Y and its polar AB and Q. Then X, Y, P, and Q are a HARMONIC RANGE (Wells 1991). Furthermore, if two lines through a pole P meet a conic at points Q and R and points S and T, then the lines QT and SR meet on the polar, as do the lines QS and RT.

The concept can be generalized even further to an arbitrary ALGEBRAIC CURVE so that every point has a polar with respect to the curve and every line has a pole (Wells 1991).

Pollaczek Polynomial

Let $a > |b|$, and write

$$h(\theta) = \frac{a \cos\theta + b}{2 \sin\theta}. \tag{1}$$

Then define $P_n(x;\ a,\ b)$ by the GENERATING FUNCTION

$$f(x,\ w) = f(\cos\theta, w) = \sum_{n=0}^{\infty} P_n(x;\ a,\ b) w^n$$
$$= (1 - we^{i\theta})^{-1/2+ih(\theta)} (1 - we^{i\theta})^{-1/2-ih(\theta)}. \tag{2}$$

The GENERATING FUNCTION may also be written

$$f(x,\ w) = \left(1 - 2xw + w^2\right)^{-1/2}$$
$$\times \exp\left[(ax+b) \sum_{m=1}^{\infty} \frac{w^m}{m} U_{m-1}(x)\right], \tag{3}$$

where $U_m(x)$ is a CHEBYSHEV POLYNOMIAL OF THE SECOND KIND.

Pollaczek polynomials satisfy the RECURRENCE RELATION

$$nP_n(x;\ a,\ b) = [(2n-1+2a)x + 2b] P_{n-1}(x;\ a,\ b)$$
$$-(n-1) P_{n-2}(x;\ a,\ b) \tag{4}$$

for $n = 2, 3, \ldots$with

$$P_0 = 1 \tag{5}$$

$$P_1 = (2a+1)x + 2b. \tag{6}$$

In terms of the HYPERGEOMETRIC FUNCTION ${}_2F_1(a,\ b;\ c;\ x)$,

$$P_n(\cos\theta;\ a;\ b)$$
$$= e^{in\theta}\ {}_2F_1\left(-n,\ \tfrac{1}{2} + ih(\theta);\ 1;\ 1 - e^{-2i\theta}\right). \tag{7}$$

They obey the orthogonality relation

$$\int_{-1}^{1} P_n(x;\ a,\ b) P_m(x;\ a,\ b) w(x;\ a,\ b)\, dx$$
$$= \left[n + \tfrac{1}{2}(a+1)\right]^{-1} \delta_{nm}, \tag{8}$$

where δ_{mn} is the KRONECKER DELTA, for $n,\ m = 0,\ 1,\ \ldots$, with the WEIGHT FUNCTION

$$w(\cos\theta;\ a,\ b) = e^{(2\theta-\pi)h(\theta)} \{\cosh[\pi h(\theta)]\}^{-1}. \tag{9}$$

Pollard Monte Carlo Factorization Method

POLLARD RHO FACTORIZATION METHOD

Pollard p-1 Factorization Method

A PRIME FACTORIZATION ALGORITHM which can be implemented in a single-step or double-step form. In the single-step version, PRIMES p are found if $p-1$ is a product of small PRIMES by finding an m such that

$$m \equiv c^q \pmod{n},$$

where $p-1|q$, with q a large number and $(c,\ n) = 1$. Then since $p-1|q$, $m \equiv 1 \pmod{p}$, so $p|m-1$. There is therefore a good chance that $n \nmid m-1$, in which case GCD$(m-1,\ n)$ (where GCD is the GREATEST COMMON DIVISOR) will be a nontrivial divisor of n.

In the double-step version, a PRIMES p can be factored if $p-1$ is a product of small PRIMES and a single larger PRIME.

Pollard Rho Factorization Method

A PRIME FACTORIZATION ALGORITHM also known as POLLARD MONTE CARLO FACTORIZATION METHOD. Let $x_0 = 2$, then compute

$$x_{i+1} = x_i^2 - x_i + 1 \pmod{n}.$$

If $\mathrm{GCD}(x_{2i} - x_i, n) > 1$, then n is COMPOSITE and its factors are found. In modified form, it becomes BRENT'S FACTORIZATION METHOD. In practice, almost any unfactorable POLYNOMIAL can be used for the iteration ($x^2 - 2$, however, cannot). Under worst conditions, the ALGORITHM can be very slow.

Pólya Conjecture

Let n be a POSITIVE INTEGER and $r(n)$ the number of (not necessarily distinct) PRIME FACTORS of n (with $r(1) = 0$). Let $O(m)$ be the number of POSITIVE INTEGERS $\leq m$ with an ODD number of PRIME FACTORS, and $E(m)$ the number of POSITIVE INTEGERS $\leq m$ with an EVEN number of PRIME FACTORS. Pólya conjectured that

$$L(m) \equiv E(m) - O(m) = \sum_{n=1}^{m} \lambda(n)$$

is ≤ 0, where $\lambda(n)$ is the LIOUVILLE FUNCTION.

The conjecture was made in 1919, and disproven by Haselgrove (1958) using a method due to Ingham (1942). Lehman (1960) found the first explicit counterexample, $L(906, 180, 359) = 1$, and the smallest counterexample m =906,150,257 was found by Tanaka (1980). The first n for which $L(n) = 0$ are $n = 2$, 4, 6, 10, 16, 26, 40, 96, 586, 906150256, ... (Tanaka 1980, Sloane's A028488). It is unknown if $L(x)$ changes sign infinitely often (Tanaka 1980).

Pólya Distribution

NEGATIVE BINOMIAL DISTRIBUTION

Pólya Enumeration Theorem

A very general theorem which allows the number of discrete combinatorial objects of a given type to be enumerated (counted) as a function of their "order." The most common application is in the counting of the number of GRAPHS of n nodes, TREES and ROOTED TREES with n branches, GROUPS of order n, etc. The theorem is an extension of the CAUCHY-FROBENIUS LEMMA, which is sometimes also called BURNSIDE'S LEMMA, the PÓLYA-BURNSIDE LEMMA, the CAUCHY-FROBENIUS LEMMA, or even "the LEMMA THAT IS NOT BURNSIDE'S!"

Pólya enumeration is implemented as [g, m], in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`) which returns the polynomial giving the number of colorings with M colors of a structure defined by a PERMUTATION GROUP g.

Pólya-Burnside Lemma

CAUCHY-FROBENIUS LEMMA, PÓLYA ENUMERATION THEOREM

Pólya's Random Walk Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $p(d)$ be the probability that a RANDOM WALK on a d-D lattice returns to the origin. Pólya (1921) proved that

$$p(1)=p(2)=1, \tag{1}$$

but

$$p(d)<1 \tag{2}$$

for $d>2$. Watson (1939), McCrea and Whipple (1940), Domb (1954), and Glasser and Zucker (1977) showed that

$$p(3)=1-\frac{1}{u(3)}=0.3405373296\ldots, \tag{3}$$

where

$$u(3)=\frac{3}{(2\pi)^3}\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}\frac{dx\,dy\,dz}{3-\cos x-\cos y-\cos z} \tag{4}$$

$$=\frac{12}{\pi^2}\left(18+12\sqrt{2}-10\sqrt{3}-7\sqrt{6}\right)$$
$$\times\left\{K\left[\left(2-\sqrt{3}\right)\left(\sqrt{3}-\sqrt{2}\right)\right]\right\}^2 \tag{5}$$

$$=3\left(18+12\sqrt{2}-10\sqrt{3}-7\sqrt{6}\right)$$
$$\times\left[1+2\sum_{k=1}^{\infty}\exp\left(-k^2\pi\sqrt{6}\right)\right]^4 \tag{6}$$

$$=\frac{\sqrt{6}}{32\pi^3}\,\Gamma\left(\tfrac{1}{24}\right)\Gamma\left(\tfrac{5}{24}\right)\Gamma\left(\tfrac{7}{24}\right)\Gamma\left(\tfrac{11}{24}\right) \tag{7}$$

$$=1.5163860592\ldots. \tag{8}$$

Here, $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND and $\Gamma(z)$ is the GAMMA FUNCTION. Closed forms for $d>3$ are not known, but Montroll (1956) showed that

$$p(d)=1-[u(d)]^{-1}, \tag{9}$$

where

$$u(d)=\frac{d}{(2\pi)^d}\underbrace{\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}\cdots\int_{-\pi}^{\pi}}_{d}$$
$$\times\left(d-\sum_{k=1}^{d}\cos x_k\right)^{-1}dx_1\,dx_2\,\cdots\,dx_d$$
$$=\int_0^{\infty}\left[I_0\left(\frac{t}{d}\right)\right]^d e^{-t}\,dt, \tag{10}$$

and $I_0(z)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. Numerical values of $p(d)$ from Montroll (1956) and Flajolet (Finch) are given in the following table.

d	$p(d)$
3	0.3405086322
4	0.1932016706
5	0.1351786098
6	0.1047154956
7	0.0858449341
8	0.0729126492

Polychoron

A POLYTOPE in 4-D. Polychora are bounded by polyhedra.

The NECESSARY condition for the polychoron with SCHLÄFLI SYMBOL $\{p,\ q,\ r\}$ to be a finite polytope is

$$\cos\left(\frac{\pi}{q}\right) < \sin\left(\frac{\pi}{p}\right) \sin\left(\frac{\pi}{r}\right).$$

SUFFICIENCY can be established by consideration of the six figures satisfying this condition.

Nine of the ten star polychora can be obtained by faceting {3, 3, 5}; in other words, they have the same vertices as {3, 3, 5}. The tenth, {5/2, 3, 3}, can be obtained by faceting {5, 3, 3}. In addition, of the ten regular star polychora, several share the same edges: {3, 3, 5}, {3, 5, 5/2}, {5, 5/2, 5}, and {5, 3, 5/2}; {3, 3, 5/2}, {3, 5/2, 5}, {5/2, 5, 5/2}, and {5/2, 3, 5}; and {5/2, 5, 3} and {5, 5/2, 3}. {5/2, 3, 3} does not share edges with any other regular polychora. There are therefore only four different projections (into any given plane or 3-space) of the ten regular star polychora, illustrated above.

Polyconic Projection

A class of map projections in which the parallels are represented by a system of non-concentric circular arcs with centers lying on the straight line representing the central meridian (Lee 1944). The term was first applied by Hunt, and later extended by Tissot (1881).

$$x = \cot\phi \sin E \tag{1}$$

$$y = (\phi - \phi_0) + \cot\phi(1 - \cos E), \tag{2}$$

where

$$E = (\lambda - \lambda_0) \sin\phi. \tag{3}$$

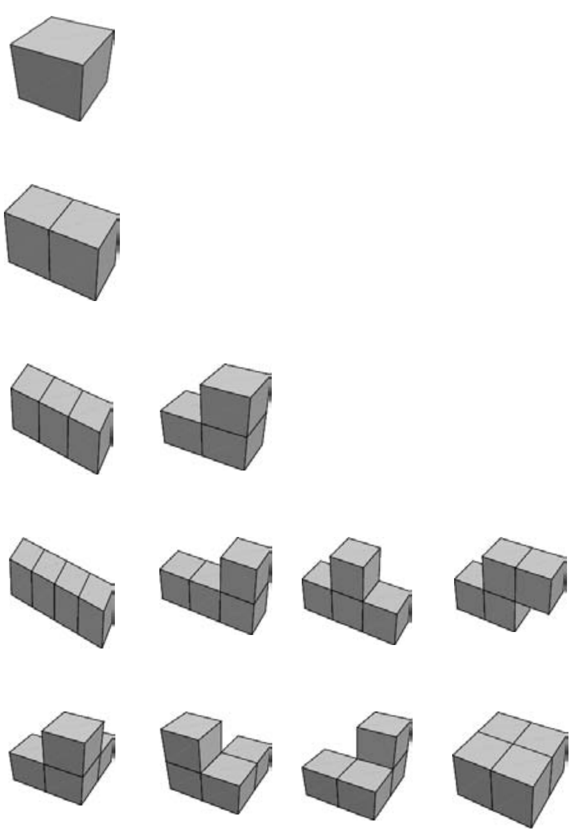
The inverse FORMULAS are

$$\lambda = \frac{\sin^{-1}(x \tan\phi)}{\sin\phi} + \lambda_0, \tag{4}$$

and ϕ is determined from

$$\Delta\phi = -\frac{A(\phi \tan\phi + 1) - \phi - \frac{1}{2}(\phi^2 + B)\tan\phi}{\frac{\phi - A}{\tan\phi} - 1}, \qquad (5)$$

where $\phi_0 = A$ and



$$A = \phi_0 + y \qquad (6)$$

$$B = x^2 + A^2. \qquad (7)$$

Polycube

3-D generalization of the POLYOMINOES to n-D. The number of polycubes $N(n)$ composed of n CUBES are 1, 1, 2, 8, 29, 166, 1023, ... (Sloane's A000162, Ball and Coxeter 1987).

There are 1390 distinct ways to pack the eight polycubes of order $n = 4$ into a $2 \times 4 \times 4$ box (Beeler 1972).

Polyfrob

POLYHEX

Polygamma Function

A SPECIAL FUNCTION which is given by the $(n+1)$st DERIVATIVE of the LOGARITHM of the GAMMA FUNCTION $\Gamma(z)$ (or, depending on the definition, of the FACTORIAL $z!$). This is equivalent to the nth normal derivative of the LOGARITHMIC DERIVATIVE of $\Gamma(z)$ (or $z!$) and, in the former case, to the nth normal derivative of the DIGAMMA FUNCTION $\psi_0(z)$. Because of this ambiguity in definition, two different notations are sometimes (but not always) used, namely

$$\psi_n(z) = \frac{d^{n+1}}{dz^{n+1}} \ln[\Gamma(z)]$$

$$= \frac{d^n}{dz^n} \frac{\Gamma'(z)}{\Gamma(z)} = \frac{d^n}{dz^n} \psi_0(z) \tag{1}$$

$$= (-1)^{n+1} n! \sum_{k=0}^{\infty} \frac{1}{(z+k)^{n+1}} \tag{2}$$

$$= (-1)^{n+1} n! \zeta(n+1, z), \tag{3}$$

where $\zeta(a, z)$ is the HURWITZ ZETA FUNCTION, and

$$F_n(z) \equiv \frac{d^{n+1}}{dz^{n+1}} \ln z!. \tag{4}$$

The two notations are connected by

$$\psi_n(z) = F_n(z-1). \tag{5}$$

Unfortunately, Morse and Feshbach (1953) adopt a notation no longer in standard use in which Morse and Feshbach's "$\psi_n(z)$" is equal to $\psi_{n-1}(z)$ in the usual notation. Also note that the function $\psi_0(z)$ is equivalent to the DIGAMMA FUNCTION $\Psi(z)$. $\psi_n(z)$ is implemented in *Mathematica* as `PolyGamma[n, z]`.

The polygamma function obeys the RECURRENCE RELATION

$$\psi_n(z+1) = \psi_n(z) + (-1)^n n! z^{-n-1}, \tag{6}$$

the reflection FORMULA

$$\psi_n(1-z) + (-1)^{n+1} \psi_n(z) = (-1)^n \pi \frac{d^n}{dz^n} \cot(\pi z), \tag{7}$$

and the multiplication FORMULA,

$$\psi_n(mz) = \delta_{n0} \ln m + \frac{1}{m^{n+1}} \sum_{k=1}^{m-1} \psi_n\left(z + \frac{k}{m}\right), \tag{8}$$

where δ_{mn} is the KRONECKER DELTA.

In general, special values for integral indices are given by

$$\psi_n(1) = (-1)^{n+1} n! \zeta(n+1) \tag{9}$$

$$\psi_n\left(\tfrac{1}{2}\right) = (-1)^{n+1} n! (2^{n+1} - 1) \zeta(n+1), \tag{10}$$

giving

$$\psi_1\left(\tfrac{1}{2}\right) = \tfrac{1}{2}\pi^2 \tag{11}$$

$$\psi_1(1) = \zeta(2) = \tfrac{1}{6}\pi^2 \tag{12}$$

$$\psi_2(1) = -2\zeta(3), \tag{13}$$

$$\psi_3\left(\tfrac{1}{2}\right) = \pi^4 \tag{14}$$

and so on.

The polygamma function can be expressed in terms of CLAUSEN FUNCTIONS for RATIONAL arguments and integer indices. Special cases are given by

$$\psi_1\left(\tfrac{1}{3}\right) = \tfrac{2}{3}\pi^2 + 3\sqrt{3}\, Cl_2\left(\tfrac{2}{3}\pi\right) \tag{15}$$

$$\psi_1\left(\tfrac{2}{3}\right) = \tfrac{2}{3}\pi^2 - 3\sqrt{3}\, Cl_2\left(\tfrac{2}{3}\pi\right) \tag{16}$$

$$\psi_1\left(\tfrac{1}{4}\right) = \pi^2 + 8\, Cl_2\left(\tfrac{1}{2}\pi\right) \tag{17}$$

$$= \pi^2 + 8K \tag{18}$$

$$\psi_1\left(\tfrac{3}{4}\right) = \pi^2 - 8\, Cl_2\left(\tfrac{1}{2}\pi\right) \tag{19}$$

$$= \pi^2 - 8K \tag{20}$$

$$\psi_2\left(\tfrac{1}{2}\right) = -8[Cl_3(0) - Cl_3(\pi)] \tag{21}$$

$$= 14\zeta(3) \tag{22}$$

$$\psi_2\left(\tfrac{1}{3}\right) = -\frac{4\pi^3}{3\sqrt{3}} - 18\, Cl_3(0) + 18\, Cl_3\left(\tfrac{2}{3}\pi\right) \tag{23}$$

$$\psi_2\left(\tfrac{2}{3}\right) = \frac{4\pi^3}{3\sqrt{3}} - 18\, Cl_3(0) + 18\, Cl_3\left(\tfrac{2}{3}\pi\right) \tag{24}$$

$$\psi_2\left(\tfrac{1}{4}\right) = -2\pi^3 - 32[Cl_3(0) - Cl_3(\pi)] \tag{25}$$

$$= -2\pi^3 - 56\zeta(3) \tag{26}$$

$$\psi_2\left(\tfrac{3}{4}\right) = 2\pi^3 - 32[Cl_3(0) - Cl_3(\pi)] \tag{27}$$

$$= 2\pi^3 - 56\zeta(3) \tag{28}$$

$$\psi_2\left(\tfrac{1}{6}\right) = -182\zeta(3) - 4\sqrt{3}\,\pi^3 \tag{29}$$

$$\psi_2\left(\tfrac{5}{6}\right) = -182\zeta(3) + 4\sqrt{3}\,\pi^3 \tag{30}$$

$$\psi_3\left(\tfrac{1}{3}\right) = \tfrac{8}{3}\,\pi^4 + 162\sqrt{3}\,Cl_4\left(\tfrac{2}{3}\,\pi\right) \tag{31}$$

$$\psi_3\left(\tfrac{2}{3}\right) = \tfrac{8}{3}\,\pi^4 - 162\sqrt{3}\,Cl_4\left(\tfrac{2}{3}\,\pi\right) \tag{32}$$

$$\psi_3\left(\tfrac{1}{4}\right) = 8\pi^4 + 768\,Cl_4\left(\tfrac{1}{2}\,\pi\right) \tag{33}$$

$$= 8\pi^4 + 768\beta(4) \tag{34}$$

$$\psi_3\left(\tfrac{3}{4}\right) = 8\pi^4 - 768\,Cl_4\left(\tfrac{1}{2}\,\pi\right) \tag{35}$$

$$= 8\pi^4 - 768\beta(4), \tag{36}$$

where K is CATALAN'S CONSTANT, $\zeta(z)$ is the RIEMANN ZETA FUNCTION, and $\beta(z)$ is the DIRICHLET BETA FUNCTION.

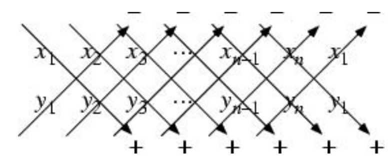
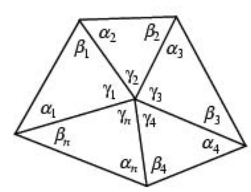
Polygon

A closed plane figure with n sides. If all sides and angles are equivalent, the polygon is called REGULAR. Polygons can be CONVEX, concave, or STAR. The word "polygon" derives from the Greek $\pi o\lambda\upsilon$ (*poly*) meaning "many" and $\gamma\omega\nu\iota\alpha$ (*gonia*) meaning "angle."

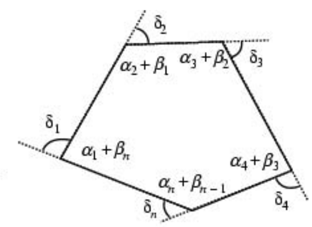


The AREA of a planar CONVEX POLYGON with VERTICES (x_1, y_1), ..., (x_n, y_n) is

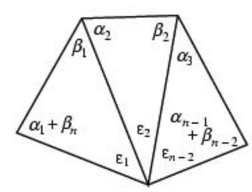
$$A = \frac{1}{2}\left(\begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix} + \begin{vmatrix} x_2 & x_3 \\ y_2 & y_3 \end{vmatrix} + \ldots + \begin{vmatrix} x_n & x_1 \\ y_n & y_1 \end{vmatrix}\right), \tag{1}$$



which can be written



$$A = \tfrac{1}{2}(x_1y_2 - x_2y_1 + x_2y_3 - x_3y_2 + \ldots + x_{n-1}y_n - x_ny_{n-1} + x_ny_1 - x_1y_n), \tag{2}$$



where the signs can be found from the following diagram.

The AREA of a polygon is defined to be POSITIVE if the points are arranged in a counterclockwise order, and NEGATIVE if they are in clockwise order (Beyer 1987).

The sum I of interior angles in the top left diagram of a dissected polygon is

$$I \equiv \sum_{i=1}^{n}(\alpha_i + \beta_i) = \sum_{i=1}^{n}(\alpha_i + \beta_i + \gamma_i) - \sum_{i=1}^{n}\gamma_i. \tag{3}$$

But

$$\sum_{i=1}^{n}\gamma_i = 360° \tag{4}$$

and the sum of ANGLES of the n TRIANGLES is

$$\sum_{i=1}^{n}(\alpha_i + \beta_i + \gamma_i) = \sum_{i=1}^{n}(180°) = n(180°). \tag{5}$$

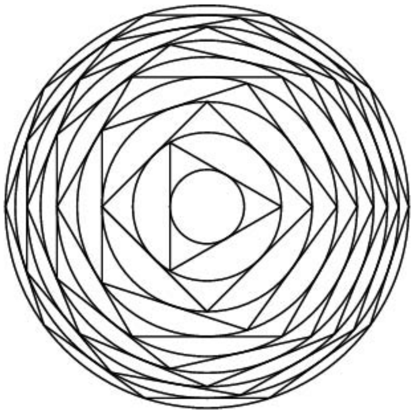
Therefore,

$$I = n(180°) - 360° = (n-2)180°. \tag{6}$$

The same equation can be derived using EXTERIOR ANGLES (top right figure) or a triangulation from a single vertex (bottom figure).

The following table gives the names for polygons with n sides. The words for polygons with $n \geq 5$ sides (e.g., PENTAGON, HEXAGON, HEPTAGON, etc.) can refer to

either REGULAR or non-regular polygons, depending on context. It is therefore always best to specify "regular n-gon" explicitly. For some polygons, several different terms are used interchangeably, e.g., nonagon and enneagon both refer to the polygon with $n = 9$ sides.



n	polygon
2	DIGON

Polygon Circumscribing Constant

If a TRIANGLE is CIRCUMSCRIBED about a CIRCLE, another CIRCLE around the TRIANGLE, a SQUARE outside the CIRCLE, another CIRCLE outside the SQUARE, and so on. From POLYGONS, the CIRCUMRADIUS and INRADIUS for an n-gon are

$$R = \tfrac{1}{2} s \csc\left(\frac{\pi}{n}\right) \quad (1)$$

$$r = \tfrac{1}{2} s \cot\left(\frac{\pi}{n}\right), \quad (2)$$

where s is the side length. Therefore,

$$\frac{R}{r} = \frac{1}{\cos\left(\frac{\pi}{n}\right)} = \sec\left(\frac{\pi}{n}\right), \quad (3)$$

and an infinitely nested set of circumscribed polygons

and circles has

$$K \equiv \frac{r_{\text{final circle}}}{r_{\text{initial circle}}} = \sec\left(\frac{\pi}{3}\right)\sec\left(\frac{\pi}{4}\right)\sec\left(\frac{\pi}{5}\right)\cdots. \quad (4)$$

Kasner and Newman (1989) and Haber (1964) state that $K = 12$, but this is incorrect. Write

$$K = \prod_{n=3}^{\infty} \frac{1}{\cos\left(\frac{\pi}{n}\right)} \quad (5)$$

$$\ln K = -\sum_{n=3}^{\infty} \ln(\cos x). \quad (6)$$

Define

$$y_0(x) \equiv -\ln(\cos x) = \tfrac{1}{2}x^2 + \tfrac{1}{12}x^4 + \tfrac{1}{45}x^6 + \tfrac{17}{2520}x^8 + \ldots \quad (7)$$

Now define

$$y_1(x) = \tfrac{1}{2}ax^2, \quad (8)$$

with

$$y_1\left(\frac{\pi}{3}\right) = y_0\left(\frac{\pi}{3}\right) \quad (9)$$

$$\tfrac{1}{2}a\left(\frac{\pi}{3}\right)^2 = \ln 2, \quad (10)$$

so

$$a = 2\left(\frac{3}{\pi}\right)^2 \ln 2, \quad (11)$$

and

$$y_2(x) = \frac{9 \ln 2}{\pi^2}x^2. \quad (12)$$

But $y_2(x) > y_1(x)$ for $x \in (0, \pi/3)$, so

$$\sum_{n=3}^{\infty} y_2\left(\frac{\pi}{n}\right) > -\sum_{n=3}^{\infty} \ln\left[\cos\left(\frac{\pi}{n}\right)\right] \quad (13)$$

$$\ln K < \sum_{n=3}^{\infty} y_2\left(\frac{\pi}{n}\right) \frac{9\ln 2}{\pi^2}\sum_{n=3}^{\infty}\left(\frac{\pi}{n}\right)^2 = 9\ln 2 \sum_{n=3}^{\infty}\frac{1}{n^2}$$

$$= 9\ln 2\left(\sum_{n=1}^{\infty}\frac{1}{n^2} - \sum_{n=1}^{2}\frac{1}{n^2}\right) = 9\ln 2\left[\zeta(2) - \tfrac{5}{4}\right]$$

$$= 9\ln 2\left(\frac{\pi^2}{6} - \frac{5}{4}\right) = 2.4637 \quad (14)$$

$$K < e^{2.4637} = 11.75. \quad (15)$$

If the next term is included,

$$y_2(x) = a\left(\tfrac{1}{2}x^2 + \tfrac{1}{12}x^4\right). \quad (16)$$

As before,

$$y_2\left(\frac{\pi}{3}\right) = y_0\left(\frac{\pi}{3}\right) \quad (17)$$

$$a = \frac{972 \ln 2}{\pi^2(54 + \pi^2)}, \quad (18)$$

so

$$y_2(x) = \frac{972\ln 2}{\pi^2(54+\pi^2)}\left(\tfrac{1}{2}x^2 + \tfrac{1}{12}x^4\right) \quad (19)$$

$$\ln K < \frac{972\ln 2}{\pi^2(54+\pi^2)}\sum_{n=3}^{\infty}\left[\frac{1}{2}\left(\frac{\pi}{n}\right)^2 + \frac{1}{12}\left(\frac{\pi}{n}\right)^4\right]$$

$$= \frac{972\ln 2}{\pi^2(54+\pi^2)}\left\{\frac{1}{2}\left[\zeta(2) - \frac{5}{4}\right] + \frac{\pi^2}{12}\left[\zeta(4) - 1 - \frac{1}{2^4}\right]\right\}$$

$$= \frac{972\ln 2}{\pi^2(54+\pi^2)}\left[\frac{1}{2}\left(\frac{\pi^2}{6} - \frac{5}{4}\right) + \frac{\pi^2}{12}\left(\frac{\pi^2}{90} - 1 - \frac{1}{2^4}\right)\right]$$

$$= \frac{9(8\pi^6 - 45\pi^2 - 5400)\ln 2}{80(\pi^2 + 54)} = 2.255, \quad (20)$$

and

$$K < e^{2.255} = 9.535. \quad (21)$$

The process can be automated using computer algebra, and the first few bounds are 11.7485, 9.53528, 8.98034, 8.8016, 8.73832, 8.71483, 8.70585, 8.70235, 8.70097, and 8.70042. In order to obtain this accuracy by direct multiplication of the terms, more than 10,000 terms are needed. The limit is

$$K = 8.700036625\ldots. \quad (22)$$

Bouwkamp (1965) produced the following INFINITE PRODUCT formulas

$$K = \frac{2}{\pi}\prod_{m=1}^{\infty}\prod_{n=1}^{\infty}\left[1 - \frac{1}{m^2\left(n+\frac{1}{2}\right)^2}\right] \quad (23)$$

$$= 6\exp\left\{\sum_{k=1}^{\infty}\frac{[\lambda(2k)-1]2^{2k}\left[\zeta(2k) - 1 - 2^{-2k}\right]}{k}\right\}, \quad (24)$$

where $\zeta(x)$ is the RIEMANN ZETA FUNCTION and $\lambda(x)$ is the DIRICHLET LAMBDA FUNCTION. Bouwkamp (1965) also produced the formula with accelerated conver-

gence

$$K = \tfrac{1}{12}\sqrt{6}\,\pi^4\left(1-\tfrac{1}{2}\pi^2+\tfrac{1}{24}\pi^4\right)\left(1-\tfrac{1}{8}\pi^2+\tfrac{1}{384}\pi^4\right)$$
$$\times\csc\left(\frac{\pi^2}{\sqrt{6+2\sqrt{3}}}\right)\csc\left(\frac{\pi^2}{\sqrt{6-2\sqrt{3}}}\right)B, \qquad (25)$$

where

$$B \equiv \prod_{n=3}^{\infty}\left(1-\frac{\pi^2}{2n^2}+\frac{\pi^4}{24n^4}\right)\sec\left(\frac{\pi}{n}\right) \qquad (26)$$

(cited in Pickover 1995).

Polygon Inscribing Constant

If a TRIANGLE is inscribed in a CIRCLE, another CIRCLE inside the TRIANGLE, a SQUARE inside the CIRCLE, another CIRCLE inside the SQUARE, and so on,

$$K' \equiv \frac{r_{\text{final circle}}}{r_{\text{initial circle}}} = \cos\left(\frac{\pi}{3}\right)\cos\left(\frac{\pi}{4}\right)\cos\left(\frac{\pi}{5}\right)\cdots.$$

Numerically,

$$K' = \frac{1}{K} = \frac{1}{8.7000366252\ldots} = 0.1149420448\ldots,$$

where K is the POLYGON CIRCUMSCRIBING CONSTANT. Kasner and Newman's (1989) assertion that $K = 1/12$ is incorrect.

Let a convex POLYGON be inscribed in a CIRCLE and divided into TRIANGLES from diagonals from one VERTEX. The sum of the RADII of the CIRCLES inscribed in these TRIANGLES is the same independent of the VERTEX chosen (Johnson 1929, p. 193).

Polygon Triangle Picking

The mean area of a TRIANGLE picked inside a regular n-gon of unit area is

$$\bar{A} = \frac{9\cos^2\omega + 52\cos\omega + 44}{36n^2\sin^2\omega}, \qquad (1)$$

where $\omega \equiv 2\pi/n$ (Alikoski 1939; Solomon 1978; Croft *et al.* 1991, p. 54). Prior to Alikoski's work, only the special cases $n = 3$, 4, 6, 8, and ∞ had been determined. The first few cases are summarized in the following table, where $\bar{A}_7$ is the largest root of

$$784147392x^3 - 84015792x^2 + 2125620x - 15289 = 0, \qquad (2)$$

and $\bar{A}_9$ is the largest root of

$$24794911296x^3 - 2525407632x^2 + 55366092x - 312427 = 0. \qquad (3)$$

n	$\bar{A}_n$	problem
3	$\frac{1}{12}$	TRIANGLE TRIANGLE PICKING
4	$\frac{11}{144}$	SQUARE TRIANGLE PICKING
5	$\frac{1}{180}(9+2\sqrt{5})$	

6	$\frac{289}{3888}$	HEXAGON TRIANGLE PICKING

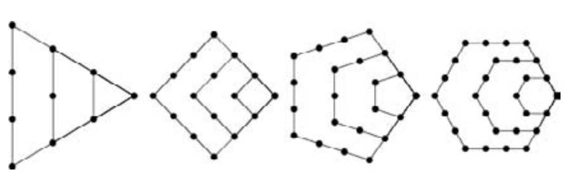
Polygon Triangulation

EULER'S POLYGON DIVISION PROBLEM, TESSELLATION, TRIANGULATION

Polygonal Knot

A KNOT equivalent to a POLYGON in $\mathbb{R}^3$, also called a TAME KNOT. For a polygonal knot K, there exists a PLANE such that the orthogonal projection π on it satisfies the following conditions:



1. The image $\pi(K)$ has no multiple points other than a FINITE number of double points.
2. The projections of the vertices of K are not double points of $\pi(K)$.

Such a projection $\pi(K)$ is called a regular knot projection.

Polygonal Number

A type of FIGURATE NUMBER which is a generalization of TRIANGULAR, SQUARE, etc., numbers to an arbitrary n-gonal number. The above diagrams graphically illustrate the process by which the polygonal numbers are built up. Starting with the nth TRIANGULAR NUMBER T_n, then

$$n+T_{n-1}=T_n. \tag{1}$$

Now note that

$$n+2T_{n-1}=n^2=S_n \tag{2}$$

gives the nth SQUARE NUMBER,

$$n+3T_{n-1}=\tfrac{1}{2}n(3n-1)=P_n, \tag{3}$$

gives the nth PENTAGONAL NUMBER, and so on. The general polygonal number can be written in the form

$$p_r^n=\tfrac{1}{2}r[(r-1)n-2(r-2)]=\tfrac{1}{2}r[(n-2)r-(n-4)], \tag{4}$$

where p_r^n is the rth n-gonal number (Savin 2000). For example, taking $n=3$ in (4) gives a TRIANGULAR NUMBER, $n=4$ gives a SQUARE NUMBER, etc.

Fermat proposed that every number is expressible as *at most* k k-gonal numbers (FERMAT'S POLYGONAL NUMBER THEOREM). Fermat claimed to have a proof of this result, although this proof has never been found. Jacobi, Lagrange (1772), and Euler all proved the square case, and Gauss proved the triangular case in 1796. In 1813, Cauchy proved the proposition in its entirety.

An arbitrary number N can be checked to see if it is a n-gonal number as follows. Note the identity

$$8(n-2)p_n^r+(n-4)^2=(2rn-4r-n+4)^2, \tag{5}$$

so $8(n-2)N+(n-4)^2=S^2$ must be a PERFECT SQUARE. Therefore, if it is not, the number cannot be n-gonal. If it is a PERFECT SQUARE, then solving

$$S=2rn-4r-n+4 \tag{6}$$

for the rank r gives

$$r=\frac{S+n-4}{2(n-2)}. \tag{7}$$

An n-gonal number is equal to the sum of the $(n-1)$-gonal number of the same RANK and the TRIANGULAR NUMBER of the previous RANK.

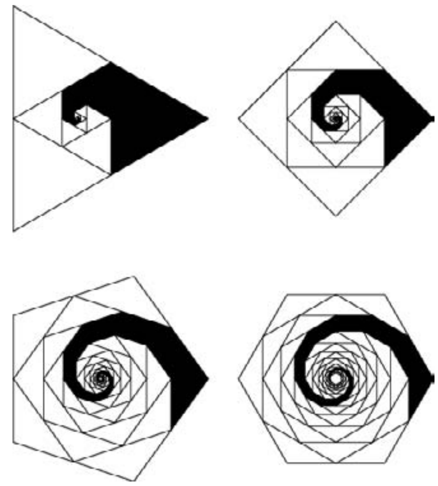
Polygonal Spiral



The length of the polygonal spiral is found by noting that the ratio of INRADIUS to CIRCUMRADIUS of a REGULAR POLYGON of n sides is

$$\frac{r}{R}=\frac{\cot\left(\frac{\pi}{n}\right)}{\csc\left(\frac{\pi}{n}\right)}=\cos\left(\frac{\pi}{n}\right). \tag{1}$$

The total length of the spiral for an n-gon with side length s is therefore

$$L=\tfrac{1}{2}s\sum_{k=0}^{\infty}\cos^k\left(\frac{\pi}{n}\right)=\frac{s}{2\left[1-\cos\left(\frac{\pi}{n}\right)\right]}. \tag{2}$$

Consider the solid region obtained by filling in subsequent triangles which the spiral encloses. The AREA of this region, illustrated above for n-gons of side length s, is

$$A=\tfrac{1}{4}s^2\cot\left(\frac{\pi}{n}\right). \tag{3}$$

The shaded triangular polygonal spiral is a REP-4-TILE.

Polyhedral Formula

A formula relating the number of VERTICES V, FACES F, and EDGES E of a simply connected (i.e., GENUS 0) POLYHEDRON (or POLYGON). It was discovered independently by Euler (1752) and Descartes, so it is also known as the Descartes-Euler polyhedral formula. Although the formula holds for some non-CONVEX POLYHEDRA, it does not hold for STELLATED POLYHEDRA.

The polyhedral formula states

$$V + F - E = 2, \tag{1}$$

where $V = N_0$ is the number of VERTICES, $E = N_1$ is the number of EDGES, and $F = N_2$ is the number of FACES. For a proof, see Courant and Robbins (1978, pp. 239–40).

The FORMULA was generalized to n-D POLYTOPES by Schläfli (Coxeter 1968, p. 233),

$$\Pi_1 : N_0 = 2 \tag{2}$$

$$\Pi_2 : N_0 - N_1 = 0 \tag{3}$$

$$\Pi_3 : N_0 - N_1 + N_2 = 2 \tag{4}$$

$$\Pi_4 : N_0 - N_1 + N_2 - N_3 = 0 \tag{5}$$

$$\Pi_n : N_0 - N_1 + N_2 - \ldots + (-1)^{n-1} N_{n-1} = 1 - (-1)^n. \tag{6}$$

and proved by Poincaré (Poincaré 1893; Coxeter 1973, pp. 166–71; Williams 1979, pp. 24–5).

For GENUS g surfaces, the formula can be generalized to the POINCARÉ FORMULA

$$\chi \equiv V - E + F = \chi(g), \tag{7}$$

where

$$\chi(g) = 2 - 2g, \tag{8}$$

is the EULER CHARACTERISTIC, sometimes also known as the EULER-POINCARÉ CHARACTERISTIC. The polyhedral formula corresponds to the special case $g = 0$.

There exist polytopes which do not satisfy the polyhedral formula, the most prominent of which are the GREAT DODECAHEDRON $\{5, \frac{5}{2}\}$ and SMALL STELLATED DODECAHEDRON $\{\frac{5}{2}, 5\}$, which no less than Schläfli himself refused to recognize (Schläfli 1901, p. 134) since for these solids,

$$N_0 - N_1 + N_2 = 12 - 30 + 12 = -6 \tag{9}$$

(Coxeter 1973, p. 172).

Polyhedral Graph

An n-polyhedral graph (sometimes called a c-net) is a 3-CONNECTED SIMPLE PLANAR GRAPH on n nodes. Every CONVEX POLYHEDRON can be represented in the plane or on the surface of a sphere by a 3-connected PLANAR GRAPH. Conversely, by a theorem of Steinitz as restated by Grünbaum (1967, p. 235), every 3-connected planar graph can be realized as a CONVEX POLYHEDRON (Duijvestijn and Federico 1981). Polyhedral graphs are sometimes simply known as "polyhedra" (which is rather confusing since the term "polyhedron" more commonly refers to a solid with n *faces*, not n vertices).

The number of distinct polyhedral graphs having $V = 1, 2, \ldots$ vertices (or equivalently $F = 1, 2, \ldots$ faces) are 0, 0, 0, 1, 2, 7, 34, 257, 2606, ... (Sloane's A000944; Grünbaum 1967, p. 424; Duijvestijn and Federico 1981; Dillencourt 1992; Croft *et al.* 1994). There is therefore a single TETRAHEDRAL GRAPH, two PENTAHEDRAL GRAPHS, etc. There is no known formula for enumerating the number of nonisomorphic polyhedral graphs by numbers of edges E, vertices V, or faces F (Harary and Palmer 1973, p. 224; Duijvestijn and Federico 1981).

V	#	graph name
4	1	TETRAHEDRAL GRAPH
5	2	PENTAHEDRAL GRAPH
6	7	HEXAHEDRAL GRAPH
7	34	HEPTAHEDRAL GRAPH
8	257	OCTAHEDRAL GRAPH
9	2606	NONAHEDRAL GRAPH
10	32300	DECAHEDRAL GRAPH

Duijvestijn and Federico (1981) enumerated the polyhedral graphs on E edges, obtaining 1, 0, 1, 2, 2, 4, 12, 22, 58, 158, 448, ... (Sloane's A002840) for $E = 6, 7, 8, ...$

Polyhedral Group

One of the symmetry groups of the PLATONIC SOLIDS. There are three polyhedral groups: the TETRAHEDRAL GROUP of order 12, the OCTAHEDRAL GROUP of order 24, and the ICOSAHEDRAL GROUP of order 60.

Polyhedron

The word polyhedron has slightly different meanings in geometry and ALGEBRAIC GEOMETRY. In geometry, a polyhedron is simply a 3-D solid which consists of a collection of POLYGONS, usually joined at their EDGES. The word derives from the Greek *poly* (many) plus the Indo-European *hedron* (seat). A polyhedron is the 3-D version of the more general POLYTOPE (in the geometric sense), which can be defined in arbitrary dimension. The plural of polyhedron is "polyhedra" (or sometimes "polyhedrons").

The term "polyhedron" is used somewhat differently in ALGEBRAIC TOPOLOGY, where it is defined as a space that can be built from such "building blocks" as line segments, triangles, tetrahedra, and their higher dimensional analogs by "gluing them together" along their faces (Munkres 1993, p. 2). More specifically, it can be defined as the UNDERLYING SPACE of a SIMPLICIAL COMPLEX (with the additional constraint sometimes imposed that the complex be finite; Munkres 1993, p. 9). In the usual definition, a polyhedron can be viewed as an intersection of half-spaces, while a POLYTOPE is a *bounded* polyhedron.

A CONVEX POLYHEDRON can be formally defined as the set of solutions to a system of linear inequalities

$$\mathsf{m}\mathbf{x} \leq \mathbf{b},$$

where m is a real $s \times 3$ MATRIX and $\mathbf{b}$ is a real s-VECTOR. Although usage varies, most authors additional require that a solution be bounded for it to define a CONVEX POLYHEDRON. An example of a convex polyhedron is illustrated above.

A polyhedron is said to be regular if its FACES and VERTEX FIGURES are REGULAR (not necessarily CONVEX) polygons (Coxeter 1973, p. 16). Using this definition, there are a total of nine REGULAR POLYHEDRA, five being the CONVEX PLATONIC SOLIDS and four being the CONCAVE (stellated) KEPLER-POINSOT SOLIDS. However, the term "regular polyhedra" is sometimes used to refer exclusively to the PLATONIC SOLIDS (Cromwell 1997, p. 53). The DUAL POLYHEDRA of the PLATONIC SOLIDS are not new polyhedra, but are themselves PLATONIC SOLIDS.

A CONVEX polyhedron is called SEMIREGULAR if its FACES have a similar arrangement of nonintersecting regular plane CONVEX polygons of two or more different types about each VERTEX (Holden 1991, p. 41). These solids are more commonly called the ARCHIMEDEAN SOLIDS, and there are 13 of them. The DUAL POLYHEDRA of the ARCHIMEDEAN SOLIDS are 13 new (and beautiful) solids, sometimes called the CATALAN SOLIDS.

A QUASIREGULAR POLYHEDRON is the solid region interior to two DUAL REGULAR POLYHEDRA (Coxeter 1973, pp. 17–0). There are only two CONVEX QUASIREGULAR POLYHEDRA: the CUBOCTAHEDRON and ICOSIDODECAHEDRON. There are also infinite families of PRISMS and ANTIPRISMS.

There exist exactly 92 CONVEX POLYHEDRA with REGULAR POLYGONAL faces (and not necessarily equivalent vertices). They are known as the JOHNSON SOLIDS. Polyhedra with identical VERTICES related by a symmetry operation are known as UNIFORM POLYHEDRA. There are 75 such polyhedra in which only two faces may meet at an EDGE, and 76 in which any EVEN number of faces may meet. Of these, 37 were discovered by Badoureau in 1881 and 12 by Coxeter and Miller ca. 1930.

Polyhedra can be superposed on each other (with the sides allowed to pass through each other) to yield additional POLYHEDRON COMPOUNDS. Those made from REGULAR POLYHEDRA have symmetries which are especially aesthetically pleasing. The graphs corresponding to polyhedra skeletons are called SCHLEGEL GRAPHS.

Behnke *et al.* (1974) have determined the symmetry groups of all polyhedra symmetric with respect to their VERTICES.

Polyhedron Coloring

Define a valid "coloring" to occur when no two faces with a common EDGE share the same color. Given two colors, there is a single way to color an OCTAHEDRON (Ball and Coxeter 1987, pp. 238–39). Given three colors, there is one way to color a CUBE (Ball and Coxeter 1987, pp. 238–39) and 144 ways to color an ICOSAHEDRON (Ball and Coxeter 1987, pp. 239–42). Given four colors, there are two distinct ways to color a TETRAHEDRON (Ball and Coxeter 1987, p. 238) and four ways to color a DODECAHEDRON, consisting of two enantiomorphous ways (Steinhaus 1983, pp. 196–98; Ball and Coxeter 1987, p. 238). Given five colors, there are four ways to color an ICOSAHEDRON. Given six colors, there are 30 ways to color a CUBE (Steinhaus 1983, p. 167).

Polyhedron Compound

A polyhedron compound is an arrangement of a number of interpenetrating polyhedra, either all the same or of several distinct types, usually having visually attractive symmetric properties. The following table gives some common polyhedron compounds.

solid	vertices
CUBE 2-COMPOUND	
CUBE 3-COMPOUND	
CUBE 4-COMPOUND	
CUBE 5-COMPOUND	DODECAHEDRON
CUBE-OCTAHEDRON COMPOUND	both
DODECAHEDRON 2-COMPOUND	
DODECAHEDRON 3-COMPOUND	
DODECAHEDRON 5-COMPOUND	
DODECAHEDRON-ICOSAHEDRON COMPOUND	both
DODECAHEDRON-SMALL TRIAMBIC ICOSAHEDRON COMPOUND	both
GREAT DODECAHEDRON-SMALL STELLATED DODECAHEDRON COMPOUND	both
GREAT ICOSAHEDRON-GREAT STELLATED DODECAHEDRON COMPOUND	both
OCTAHEDRON 3-COMPOUND	
OCTAHEDRON 5-COMPOUND	ICOSIDODECAHEDRON
STELLA OCTANGULA	CUBE
TETRAHEDRON 4-COMPOUND	
TETRAHEDRON 5-COMPOUND	DODECAHEDRON
TETRAHEDRON 10-COMPOUND	DODECAHEDRON

In Coxeter's NOTATION, d distinct VERTICES of $\{m, n\}$ taken c times are denoted

$$c\{m, n\}[d\{p, q\}], \tag{1}$$

or faces of $\{s, t\}$ e times

$$[d\{p, q\}]e\{s, t\}, \tag{2}$$

or both

$$c\{m, n\}[d\{p, q\}]e\{s, t\}. \tag{3}$$

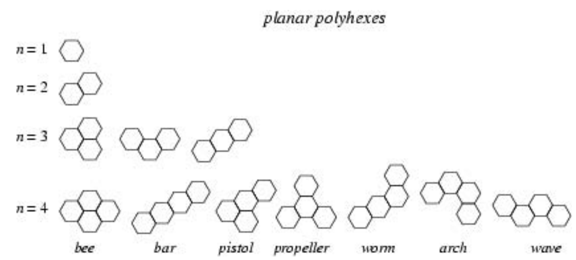
Polyhedron Dual

DUAL POLYHEDRON

Polyhedron Hinging

RIGIDITY THEOREM

Polyhedron Packing



A packing of polyhedron in 3-D space. A polyhedron which can pack with no holes or gaps is said to be a SPACE-FILLING POLYHEDRON. Betke and Henk (1999) present an efficient algorithm for computing the density of a densest lattice packing of an arbitrary polyhedron, and explicitly calculate the densities for the PLATONIC and ARCHIMEDEAN SOLIDS.

See also KELVIN'S CONJECTURE, PACKING, SPACE-FILLING POLYHEDRON

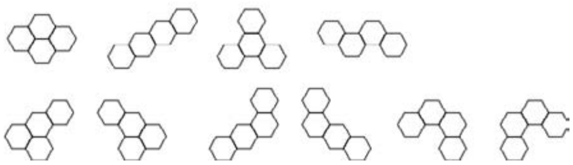
Polyhex

An analog of the POLYOMINOES and POLYIAMONDS in which collections of regular hexagons are arranged with adjacent sides. They are also called HEXES, HEXAS, or POLYFROBS (Beeler 1972). For the 4-hexes (tetrahexes), the possible arrangements are known as the BEE, BAR, PISTOL, PROPELLER, WORM, ARCH, and WAVE.



A simple connected polyhex is called a fusene. Let the number of internal vertices of a polyhex be denoted n_i. Then catafusenes (or catacondensed fusenes) have $n_i = 0$ (and are therefore also called "tree-like"), and perifusenes (or pericondensed fusenes) have $n_i = 1$. The numbers of catafusenes composed of n polyhexes are sometimes called Harary-Read numbers, and have the impressive GENERATING FUNCTION

$$H(x) = \tfrac{1}{24} x^{-2}\{12 + 24x + 48x^2 - 24x^3 + [(1-x)(1-5x)]^{3/2} - 3(5x+3) \times \sqrt{(1-x^2)(1-5x^2)} - 4\sqrt{(1-x^3)(1-5x^3)}\}$$

$$= x + x^2 + 2x^3 + 5x^4 + 12x^5 + 37x^6 + \ldots$$

(Harary and Read 1970, Cyvin *et al.* 1993). Polyhexes may also be classified on the basis of being geometrically planar (called nonhelicenic) or geometrically nonplanar (called helicenic). Fusenes include the helicenes.

one-sided 4-polyhexes

"One-sided" polyhexes are considered to be FIXED in the plane, and so mirror images are counted separately.

The following table gives the numbers of n-polyhexes that are geometrically planar (Klarner 1967, Balaban and Harary 1968, Harary and Read 1970, Lunnon 1972, Gardner 1978, Knop *et al.* 1984, Gardner 1988), catafusenes (Harary and Read 1970, Beinecke and Pippert 1974, Knop *et al.* 1984, Cyvin *et al.* 1993), cata- and planar, cata- and simply connected, and one-sided.

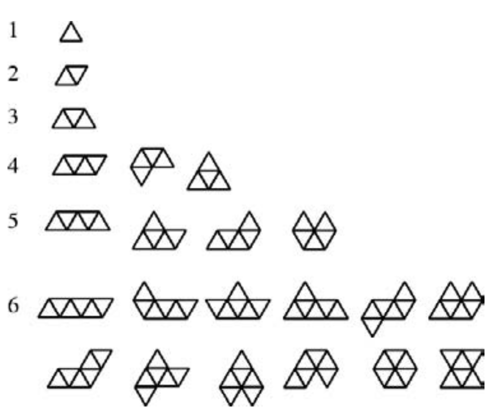
Polyhex Tiling



There are no tilings of the EQUILATERAL TRIANGLE of side length 7 by *all* the polyhexes of order $n = 4$. There are nine distinct solutions of *all* the polyhexes of order $n = 4$ which tile a PARALLELOGRAM of base length 7 and side length 4, one of which is illustrated above (Beeler 1972).

Polyiamond

A generalization of the POLYOMINOES using a collection of equal-sized EQUILATERAL TRIANGLES (instead of SQUARES) arranged with coincident sides. Polyiamonds are sometimes simply known as IAMONDS.

The number of two-sided (i.e., can be picked up and flipped, so MIRROR IMAGE pieces are considered identical) polyiamonds made up of n triangles are 1, 1, 1, 3, 4, 12, 24, 66, 160, 448, ... (Sloane's A000577). The number of one-sided polyiamonds composed of n triangles are 1, 1, 1, 4, 6, 19, 43, 121, ... (Sloane's A006534). One of the 160 9-polyiamonds has a hole (Gardner 1984, p. 174).

The top row of HEXIAMONDS in the above figure are known as the BAR, CROOK, CROWN, SPHINX, SNAKE, and YACHT. The bottom row of 6-polyiamonds are known as the CHEVRON, SIGNPOST, LOBSTER, HOOK, HEXAGON, and BUTTERFLY.

POLYPLET

PolyLog

POLYLOGARITHM

Polylogarithm

The function

$$\mathrm{Li}_n(z) \equiv \sum_{k=1}^{\infty} \frac{z^k}{k^n}, \tag{1}$$

Also known as Jonquière's function. (Note that the similar NOTATION $\mathrm{Li}(z)$ is used for the LOGARITHMIC INTEGRAL.) The polylogarithm is also denoted $F(z, n)$ and equal to

$$\mathrm{Li}_n(z) = z\Phi(z, n, 1), \tag{2}$$

where $\Phi(z, n, a)$ is the LERCH TRANSCENDENT (Erdélyi *et al.* 1981, p. 30). The polylogarithm arises in Feynman diagram integrals (and, in particular, in the computation of quantum electrodynamics corrections to the electrons gyromagnetic ratio), and the special cases $n = 2$ and $n = 3$ are called the DILOGARITHM and TRILOGARITHM, respectively.

The polylogarithm of NEGATIVE INTEGER order arises in sums OF THE FORM

$$\sum_{k=1}^{\infty} k^n r^k = \mathrm{Li}_{-n}(r) = \frac{r}{(1-r)^{n+1}} \sum_{i=1}^{n} \left\langle {n \atop i} \right\rangle r^{n-i}, \tag{3}$$

where $\left\langle {n \atop i} \right\rangle$ is an EULERIAN NUMBER.

Special forms of low-order polylogarithms include

$$\mathrm{Li}_{-2}(x) = \frac{x(x+1)}{(1-x)^3} \tag{4}$$

$$\mathrm{Li}_{-1}(x) = \frac{x}{(1-x)^2} \tag{5}$$

$$\mathrm{Li}_0(x) = \frac{x}{1-x} \tag{6}$$

$$\mathrm{Li}(x) = -\ln(1-x). \tag{7}$$

At arguments -1 and 1, the general polylogarithms become

$$\mathrm{Li}_n(-1) = -\eta(n) \tag{8}$$

$$\mathrm{Li}_n(1) = \zeta(n), \tag{9}$$

where $\eta(x)$ is the DIRICHLET ETA FUNCTION and $\zeta(x)$ is the RIEMANN ZETA FUNCTION. The polylogarithm for argument 1/2 can also be evaluated analytically for small n,

$$\mathrm{Li}_1\left(\tfrac{1}{2}\right) = \ln 2 \tag{10}$$

$$\mathrm{Li}_2\left(\tfrac{1}{2}\right) = \tfrac{1}{12}[\pi^2 - 6(\ln 2)^2] \tag{11}$$

$$\mathrm{Li}_3\left(\tfrac{1}{2}\right) = \tfrac{1}{24}[4(\ln 2)^3 - 2\pi^2 \ln 2 + 21\zeta(3)]. \tag{12}$$

No similar formulas of this type are known for higher orders (Lewin 1991, p. 2). $\mathrm{Li}_4(1/2)$ appears in the third-order correction term in the gyromagnetic ratio of the electron.

The derivative of a polylogarithm is itself a polylogarithm,

$$\frac{d}{dx}\,\mathrm{Li}_n(x) = \frac{1}{x}\,\mathrm{Li}_{n-1}(x). \tag{13}$$

Bailey *et al.* showed that

$$\frac{\mathrm{Li}_m\left(\frac{1}{64}\right)}{6^{m-1}} - \frac{\mathrm{Li}_m\left(\frac{1}{8}\right)}{3^{m-1}} - \frac{2\,\mathrm{Li}_m\left(\frac{1}{4}\right)}{2^{m-1}} + \frac{4\,\mathrm{Li}_m\left(\frac{1}{2}\right)}{9} - \frac{5(-\ln 2)^m}{9m!}$$
$$+ \frac{\pi^2(-\ln 2)^{m-2}}{54(m-2)!} - \frac{\pi^4(-\ln 2)^{m-4}}{486(m-4)!} - \frac{403\zeta(5)(-\ln 2)^{m-5}}{1296(m-5)!}$$
$$= 0. \tag{14}$$

No general ALGORITHM is know for the integration of polylogarithms of functions.

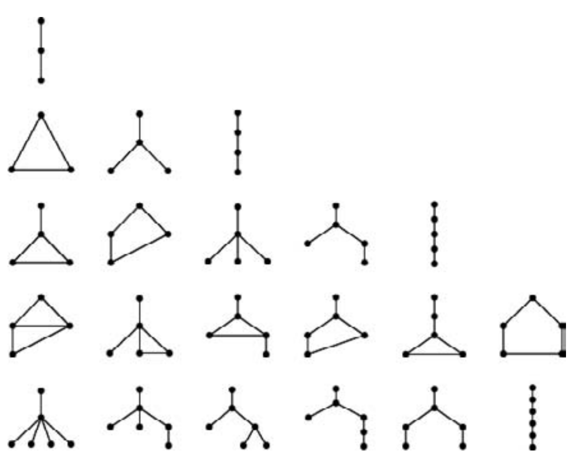
Polymorph



An INTEGER which is expressible in more than one way in the form $x^2 + Dy^2$ or $x^2 - Dy^2$ where x^2 is RELATIVELY PRIME to Dy^2. If the INTEGER is expressible in only one way, it is called a MONOMORPH.

See also ANTIMORPH, IDONEAL NUMBER, MONOMORPH, PELL EQUATION

Polymorph Tessellation

TESSELLATION

Polynema

A polynema of order n is Kyrmse's term for a CONNECTED GRAPH having n edges. An n-polynema must therefore have either n or $n+1$ nodes. The numbers of n-polynemas for $n = 1, 2$ ... are 1, 1, 3, 5, 12, 30, 79, 227, ... (Sloane's A002905). Polynemas are related to a graphical construction problem called the MATCH PROBLEM (Gardner 1991).

Polynomial

A POLYNOMIAL is a mathematical expression involving a series of POWERS in one or more variables multiplied by COEFFICIENTS. A POLYNOMIAL in one variable (i.e., a univariate polynomial) with constant COEFFICIENTS is given by

$$a_n x^n + \ldots + a_2 x^2 + a_1 x + a_0. \tag{1}$$

The highest POWER in a univariate polynomial is called its ORDER. A POLYNOMIAL in two variables (i.e., a bivariate polynomial) with constant COEFFICIENTS is given by

$$a_{nm} x^n y^m + \ldots + a_{22} x^2 y^2 + a_{21} x^2 y + a_{12} x y^2 + a_{11} xy + a_{10} x + a_{01} y + a_{00} \tag{2}$$

Exchanging the COEFFICIENTS of a univariate polynomial end-to-end produces a polynomial

$$a_0 x^n + a_1 x^{n-1} + \ldots + a_{n-1} x + a_n = 0 \tag{3}$$

whose ROOTS are RECIPROCALS $1/x_i$ of the original ROOTS x_i.

HORNER'S RULE provides a computationally efficient method of forming a polynomial from a list of its coefficients, and can be implemented in *Mathematica* as follows.

```
PolynomialFromCoefs[l_List, x_] := Fold[x#1 +
#2 &, 0, l]
```

The following table gives special names given to polynomials of low orders.

ORDER	Polynomial Type
1	LINEAR EQUATION
2	QUADRATIC EQUATION
3	CUBIC EQUATION
4	QUARTIC EQUATION
5	QUINTIC EQUATION
6	SEXTIC EQUATION

Polynomials of fourth degree may be computed using three multiplications and five additions if a few quantities are calculated first (Press *et al.* 1989):

$$a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 = [(Ax+B)^2 + Ax + C][(Ax+B)^2 + D] + E, \tag{4}$$

where

$$A \equiv (a_4)^{1/4} \tag{5}$$

$$B \equiv \frac{a_3 - A^3}{4A^3} \tag{6}$$

$$D \equiv 3B^2 + 8B^3 + \frac{a_1 A - 2a_2 B}{A^2} \tag{7}$$

$$C \equiv \frac{a_2}{A^2} - 2B - 6B^2 - D \tag{8}$$

$$E \equiv a_0 - B^4 - B^2(C + D) - CD. \tag{9}$$

Similarly, a POLYNOMIAL of fifth degree may be computed with four multiplications and five additions, and a POLYNOMIAL of sixth degree may be computed with four multiplications and seven additions.

Polynomials of orders one to four are solvable using only rational operations and finite ROOT EXTRACTIONS. A first-order equation is trivially solvable. A second-order equation is soluble using the QUADRATIC EQUATION. A third-order equation is solvable using the CUBIC EQUATION. A fourth-order equation is solvable using the QUARTIC EQUATION. It was proved by Abel and Galois using GROUP THEORY that general equations of fifth and higher order cannot be solved rationally with finite ROOT EXTRACTIONS (ABEL'S IMPOSSIBILITY THEOREM).

However, the general QUINTIC EQUATION may be given in terms of the JACOBI THETA FUNCTIONS, or HYPERGEOMETRIC FUNCTIONS in one variable. Hermite and Kronecker proved that higher order POLYNOMIALS are not soluble in the same manner. Klein showed that the work of Hermite was implicit in the GROUP properties of the ICOSAHEDRON. Klein's method of solving the quintic in terms of HYPERGEOMETRIC FUNCTIONS in one variable can be extended to the sextic, but for higher order POLYNOMIALS, either HYPERGEOMETRIC FUNCTIONS in several variables or "Siegel functions" must be used (Belardinelli 1960, King 1996, Chow 1999). In the 1880s, Poincaré created functions which give the solution to the nth order POLYNOMIAL equation in finite form. These functions turned out to be "natural" generalizations of the ELLIPTIC FUNCTIONS.

Given an nth degree polynomial, the ROOTS can be found by finding the EIGENVALUES of the MATRIX

$$\begin{bmatrix} -a_0/a_n & -a_1/a_n & -a_2/a_n & \dots & -1 \\ 1 & 0 & 0 & \dots & 0 \\ 0 & 1 & 0 & \dots & 0 \\ \vdots & \vdots & 1 & \ddots & 0 \\ 0 & 0 & 0 & \dots & 0 \end{bmatrix}. \tag{10}$$

This method can be computationally expensive, but is fairly robust at finding close and multiple roots.

Polynomial identities involving sums and differences of like POWERS include

$$x^2 - y^2 = (x - y)(x + y) \tag{11}$$

$$x^3 - y^3 = (x - y)(x^2 + xy + y^2) \tag{12}$$

$$x^3 + y^3 = (x + y)(x^2 - xy + y^2) \tag{13}$$

$$x^4 - y^4 = (x - y)(x + y)(x^2 + y^2) \tag{14}$$

$$x^5 - y^5 = (x - y)(x^4 + x^3y + x^2y^2 + xy^3 + y^4) \tag{15}$$

$$x^5 + y^5 = (x + y)(x^4 - x^3y + x^2y^2 - xy^3 + y^4) \tag{16}$$

$$x^6 - y^6 = (x - y)(x + y)(x^2 + xy + y^2)(x^2 - xy + y^2) \tag{17}$$

$$x^6 + y^6 = (x^2 + y^2)(x^4 - x^2y^2 + y^4). \tag{18}$$

Further identities include

$$\left(x_1^2 - Dy_1^2\right)\left(x_2^2 - Dy_2^2\right) = (x_1x_2 + Dy_1y_2)^2 - D(x_1y_2 + x_2y_1)^2 \tag{19}$$

$$\left(x_1^2 + Dy_1^2\right)\left(x_2^2 + Dy_2^2\right) = (x_1x_2 \pm Dy_1y_2)^2 + D(x_1y_2 \mp x_2y_1)^2. \tag{20}$$

The identity

$$(X + Y + Z)^7 - (X^7 + Y^7 + Z^7) = 7(X + Y)(X + Z)(Y + Z) \times [(X^2 + Y^2 + Z^2 + XY + XZ + YZ)^2 + XYZ(X + Y + Z)] \tag{21}$$

was used by Lamé in his proof that FERMAT'S LAST THEOREM was true for $n = 7$.

Polynomial Bar Norm

POLYNOMIAL NORM

Polynomial Bracket Norm

BOMBIERI NORM

Polynomial Curve

A curve obtained by fitting POLYNOMIALS to each ordinate of an ordered sequence of points. The above plots show POLYNOMIAL curves where the order of the fitting POLYNOMIAL varies from $p-3$ to $p-1$, where p is the number of points.

Polynomial curves have several undesirable features, including a nonintuitive variation of fitting curve with varying COEFFICIENTS, and numerical instability for high orders. SPLINES such as the BÉZIER CURVE are therefore used more commonly.

See also BÉZIER CURVE, POLYNOMIAL, SPLINE

Polynomial Equation

An EQUATION of the form

$$P(x) = 0,$$

where $P(x)$ is a POLYNOMIAL.

See also POLYNOMIAL

Polynomial Factorization

A FACTOR of a POLYNOMIAL $P(x)$ of degree n is a POLYNOMIAL $Q(x)$ of degree less than n which can be multiplied by another POLYNOMIAL $R(x)$ of degree less than n to yield $P(x)$, i.e., a POLYNOMIAL $Q(x)$ such that

$$P(x) = Q(x)R(x).$$

For example, since

$$x^2 - 1 = (x+1)(x-1),$$

both $x-1$ and $x+1$ are FACTORS of x^2-1. Polynomial factorization can be performed in *Mathematica* using `Factor[`*poly*`]`.

The COEFFICIENTS of factor POLYNOMIALS are often required to be REAL NUMBERS or INTEGERS but could, in general, be COMPLEX NUMBERS. The FUNDAMENTAL THEOREM OF ALGEBRA states that a POLYNOMIAL $P(z)$ of degree n has n values z_i (some of which are possibly degenerate) for which $P(z_i) = 0$. Such values are called POLYNOMIAL ROOTS.

Polynomial Height

The l_∞-POLYNOMIAL NORM defined for a polynomial $P = a_k x^k + \ldots + a_1 x + a_0$ by

$$\|P\|_\infty = \max_k |a_k|.$$

Note that some authors (especially in the area of Diophantine analysis) use $|P|$ as a shorthand for $\|P\|_\infty$, while others (especially in the area of computational complexity) used $|P|$ to denote the l_2-norm $\|P\|_2$ (Zippel 1993, p. 174).

See also POLYNOMIAL NORM

References

Zippel, R. "Heights of Polynomials." §11.1 in *Effective Polynomial Computation.* Boston, MA: Kluwer, pp. 174–75, 1993.

Polynomial Map

A map OF THE FORM

$$\phi_{\mathbf{f}} : K^n \to K^n$$

$$\phi_{\mathbf{f}} : (a_1, \ldots, a_n) \mapsto (f_1(\mathbf{a}), \ldots, f_1(\mathbf{a})),$$

where $\mathbf{f} = (f_1, \ldots, f_n) \in (K[X_1, \ldots, X_n])^m$ in a FIELD K, and $\mathbf{a} = (a_1, \ldots, a_n)$.

Polynomial Matrix

A MATRIX whose entries are POLYNOMIALS.

See also MATRIX POLYNOMIAL

References

Pascoletti, A. "Polynomial Matrix Utilities." http://www.mathsource.com/cgi-bin/msitem?0207–51.

Polynomial Norm

For a POLYNOMIAL

$$P = \sum_{k=0}^{n} a_k z^k, \tag{1}$$

several classes of norms are commonly defined. The l_p-norm is defined as

$$\|P\|_p \equiv \left(\sum_{k=0}^{n} |a_k|^p\right) \tag{2}$$

for $p \geq 1$, giving the special cases

$$\|P\|_1 \equiv \sum_j |a_k| \tag{3}$$

$$\|P\|_2 = \sqrt{\sum_k |a_k|^2} \tag{4}$$

$$\|P\|_\infty = \max_k |a_k|. \tag{5}$$

Here, $\|P\|_\infty$ is called the POLYNOMIAL HEIGHT. Note that some authors (especially in the area of Diophantine analysis) use $|P|$ as a shorthand for $\|P\|_\infty$ and $|P|$ as a shorthand for $\|P_2\|$, while others (especially in the area of computational complexity) used $|P|$ to denote the l_2-norm $\|P\|_2$ and (Zippel 1993, p. 174).

Another class of norms is the L_p-norms, defined by

$$\|P\|_{L_p} = \left(\int_0^{2\pi} |P(e^{i\theta})| \frac{d\theta}{2\pi}\right)^{1/p} \tag{6}$$

for $p \geq 1$, giving the special cases

$$\|P\|_{L_1} = \int_0^{2\pi} |P(e^{i\theta})| \frac{d\theta}{2\pi}$$

$$\|P\|_{L_2} = \sqrt{\int_0^{2\pi} |P(e^{i\theta})|^2 \frac{d\theta}{2\pi}}$$

$$\|P\|_{L_\infty} = \sup_{|z|=1} |P(z)|$$

(Borwein and Erdélyi 1995, p. 6).

Polynomial Remainder Theorem

If the COEFFICIENTS of the POLYNOMIAL

$$d_n x^n + d_{n-1} x^{n-1} + \ldots + d_0 = 0 \tag{1}$$

are specified to be INTEGERS, then integral ROOTS must have a NUMERATOR which is a factor of d_0 and a DENOMINATOR which is a factor of d_n (with either sign possible). This follows since a POLYNOMIAL of ORDER n with k integral ROOTS can be expressed as

$$(a_1x+b_1)(a_2x+b_2)\cdots(a_kx+b_k)(c_{n-k}x^{n-k}+\ldots+c_0) = 0, \tag{2}$$

where the ROOTS are $x_1 = -b_1/a_1$, $x_2 = -b_2/a_2$, ..., and $x_k = -b_k/a_k$. Factoring out the a_is,

$$a_1a_2\ldots a_k\left(x-\frac{b_1}{a_1}\right)\left(x-\frac{b_2}{a_2}\right)\cdots\left(x-\frac{b_k}{a_k}\right) \times(c_{n-k}x^{n-k}+\ldots+c_0) = 0. \tag{3}$$

Now, multiplying through,

$$a_1a_2\ldots a_k c_{n-k} x^n + \ldots + b_1b_2\ldots b_k c_0 = 0, \tag{4}$$

where we have not bothered with the other terms. Since the first and last COEFFICIENTS are d_n and d_0, all the integral roots of (1) are OF THE FORM [factors of d_0]/[factors of d_n].

Polynomial Ring

The RING $R[x]$ of POLYNOMIALS in a variable x.

See also MODULE, POLYNOMIAL, RING

Polynomial Roots

A root of a polynomial $P(z)$ is a number z_i such that $P(z_i) = 0$. The FUNDAMENTAL THEOREM OF ALGEBRA states that a POLYNOMIAL $P(z)$ of degree n has n roots, some of which may be degenerate. For example, the roots of the polynomial

$$x^3 - 2x^2 - x + 2 = (x-2)(x-1)(x+1) \tag{1}$$

are -1, 1, and 2. Finding roots of a polynomial is therefore equivalent to POLYNOMIAL FACTORIZATION into factors of degree 1. The roots of a polynomial equation may be found in *Mathematica* using `Roots[`*lhs* `= =` *rhs*, *var*`]`.

Let the ROOTS of the polynomial

$$P(x) \equiv a_n x^n + a_{n-1} x^{n-1} + \ldots a_1 x + a_0 \tag{2}$$

be denoted r_1, r_2, ..., r_n. Then NEWTON'S RELATIONS are

$$\sum r_i = -\frac{a_{n-1}}{a_n} \tag{3}$$

$$\sum r_i r_j = \frac{a_{n-2}}{a_n} \qquad (4)$$

$$\sum r_1 r_2 \cdots r_k = (-1)^k \frac{a_{n-k}}{a_n}. \qquad (5)$$

These can be derived by writing

$$P(x) = a_n(x - r_1)(x - r_2)\cdots(x - r_n), \qquad (6)$$

expanding, and then comparing the coefficients with (2).

Any POLYNOMIAL can be numerically factored, although different ALGORITHMS have different strengths and weaknesses.

If the COEFFICIENTS of the POLYNOMIAL

$$d_n x^n + d_{n-1}x^{n-1} + \ldots + d_0 = 0 \qquad (7)$$

are specified to be INTEGERS, then integral roots must have a NUMERATOR which is a factor of d_0 and a DENOMINATOR which is a factor of d_n (with either sign possible). This is known as the POLYNOMIAL REMAINDER THEOREM.

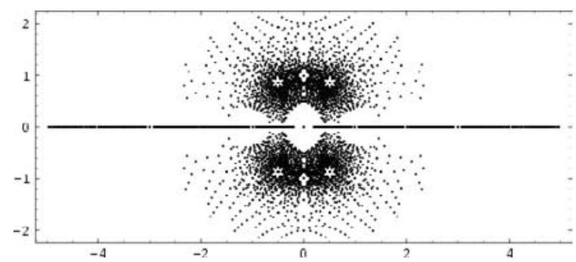
If there are no NEGATIVE ROOTS of a POLYNOMIAL (as can be determined by DESCARTES' SIGN RULE), then the GREATEST LOWER BOUND is 0. Otherwise, write out the COEFFICIENTS, let $n = -1$, and compute the next line. Now, if any COEFFICIENTS are 0, set them to minus the sign of the next higher COEFFICIENT, starting with the second highest order COEFFICIENT. If all the signs alternate, n is the greatest lower bound. If not, then subtract 1 from n, and compute another line. For example, consider the POLYNOMIAL

$$y = 2x^4 + 2x^3 - 7x^2 + x - 7. \qquad (8)$$

Performing the above ALGORITHM then gives

0	2	2	−7	1	−7
−1	2	0	−7	8	−15
−	2	−1	−7	8	−15
−2	2	−2	−3	7	−21
−3	2	−4	5	−14	35

so the greatest lower bound is -3.



If there are no POSITIVE ROOTS of a POLYNOMIAL (as can be determined by DESCARTES' SIGN RULE), the LEAST UPPER BOUND is 0. Otherwise, write out the COEFFICIENTS of the POLYNOMIALS, including zeros as necessary. Let $n = 1$. On the line below, write the highest order COEFFICIENT. Starting with the second-highest COEFFICIENT, add n times the number just written to the original second COEFFICIENT, and write it below the second COEFFICIENT. Continue through order zero. If all the COEFFICIENTS are NONNEGATIVE, the least upper bound is n. If not, add one to x and repeat the process again. For example, take the POLYNOMIAL

$$y = 2x^4 - x^3 - 7x^2 + x - 7. \qquad (9)$$

Performing the above ALGORITHM gives

0	2	−1	−7	1	−7
1	2	1	−6	−5	−12
2	2	3	−1	−1	−9
3	2	5	8	25	68

so the LEAST UPPER BOUND is 3.

Plotting the roots in the complex plane of all polynomials up to some degree with integer coefficients less than some cutoff integer in absolute value shows the beautiful structure illustrated above (Trott 2000).

Polyomino

A generalization of the DOMINO, originally called "super-dominoes" by Gardner (1957). An n-polyomino (or "n-omino"rpar; is defined as a collection of n squares of equal size arranged with coincident sides. FREE polyominoes can be picked up and flipped, so mirror image pieces are considered identical, whereas FIXED polyominoes are distinct if they have different chirality or orientation. FIXED polyominoes are also called LATTICE ANIMALS.

Redelmeier (1981) computed the number of FREE and FIXED polyominoes for $n \leq 24$, and Mertens (1990) gives a simple computer program. The following table gives the number of FREE (Lunnon 1971, 1972; Read 1978; Redelmeier 1981; Ball and Coxeter 1987; Conway and Guttmann 1995; Goodman and O'Rourke 1997, p. 229), FIXED (Redelmeier 1981), one-sided (i.e., chiral) polyominoes (Redelmeier 1981; Golomb 1994; Goodman and O'Rourke 1997, p. 229), as well as the number of possible holes (Parkin *et al.* 1967, Madachy 1969, Golomb 1994) for the first few n

24	654999700403	5239988770268	1309998125640	

The best currently known bounds on the number of n-polyominoes are

$$3.72^n < P(n) < 4.65^n$$

(Eden 1961, Klarner 1967, Klarner and Rivest 1973, Ball and Coxeter 1987).

There is a single unique 2-omino (the DOMINO), and two distinct 3-ominoes (the straight- and L-TRIOMINOES). The 4-ominoes (TETROMINOES) are known as the STRAIGHT, L, T, SQUARE, and SKEW TETROMINOES. The 5-ominoes (PENTOMINOES) are called f, I, L, N, P, T, U, V, W, X, y, and Z (Golomb 1995). Another common naming scheme replaces f, I, L, and N with R, O, Q, and S so that all letters from O to Z are used (Berlekamp *et al.* 1982).

Polyomino Tiling

A TILING of the PLANE by specified types of POLYOMINOES. Interestingly, the FIBONACCI NUMBER F_{n+1} gives the number of ways for 2×1 DOMINOES to cover a $2 \times n$ checkerboard. Each MONOMINO, DOMINO, TRIOMINO, TETROMINO, PENTOMINO, and HEXOMINO tiles the plane, with requiring flipping. In addition, each heptomino, with the exception of the four illustrated above, can tile the plane, also without flipping (Schroeppel 1972).

Consider now those collections of *all* n-ominoes which form a RECTANGLE. The polynomials of orders $n = 1$ and $n = 2$ form only a SQUARE and RECTANGLE, respectively. The two polyominoes of order $n = 3$ cannot form a rectangle, nor can the five polyominoes of order $n = 4$ or the 35 polyominoes of order $n = 6$ (Beeler 1972). There are several rectangles formed by the 12 polyominoes of order $n = 5$, as summarized in the following table (Beeler 1972).

Size	Solutions
3×20	2
4×15	368
5×12	1010
6×10	2339
$2\ 5 \times 6$	2
8×8 with 2×2 hole	65

Polyplet

A polyomino-like object made by attaching squares joined either at sides or corners. Because neighboring squares can be in relation to one another as kings may move on a chessboard, polyplets are sometimes also called polykings. The number of n-polyplets (with holes allowed) are 1, 2, 5, 22, 94, 524, 3031, ... (Sloane's A030222). The number of n-polyplets having bilateral symmetry are 1, 2, 4, 10, 22, 57, 131, ... (Sloane's A030234). The number of n-polyplets not having bilateral symmetry are 0, 0, 1, 12, 72, 467, 2900, ... (Sloane's A030235). The number of fixed n-polyplets are 1, 4, 20, 110, 638, 3832, ... (Sloane's A030232). The number of one-sided n-polyplets are 1, 2, 6, 34, 166, 991, ... (Sloane's A030233).

Polytopal Graph

A graph G is called d-polytopal if there exists a d-dimensional convex polytope P such that the vertices and edges of G are in a one-to-one incidence-preserving correspondence with those of P. In other words G is d-polytopal iff it is isomorphic to the 1-skeleton of some convex d-polytopes P. If $d = 3$, the graph is called a polyhedral graph.

Polytope

The word polytope is used to mean a number of related, but slightly different mathematica objects. A convex polytope may be defined as the convex hull of a finite set of points (which are always bounded), or as a *bounded* intersection of a finite set of half-spaces. Coxeter (1973, p. 118) defines polytope as the general term of the sequence "point, line segment, polygon, polyhedron, ...," or more specifically as a finite region of n-dimensional space enclosed by a finite number of hyperplanes. The special name polychoron is sometimes given to a 4-D polytope. However, in algebraic topology, the underlying space of a simplicial complex is sometimes called a polytope (Munkres 1993, p. 8). The word "polytope" was introduced by Alicia Boole, the somewhat colorful daughter of logician George Boole (MacHale 1985).

The part of the polytope that lies in one of the bounding hyperplanes is called a cell. A 4-D polytope is sometimes called a polychoron. Explicitly, a d-dimensional polytope may be specified as the set of solutions to a system of linear inequalities

$$\mathsf{m}\mathbf{x} \leq \mathbf{b},$$

where m is a real $s \times d$ matrix and $\mathbf{b}$ is a real s-vector. The positions of the vertices given by the above equations may be found using a process called vertex enumeration.

A regular polytope is a generalization of the Platonic solids to an arbitrary dimension. The regular polytopes were discovered before 1852 by the Swiss mathematician Ludwig Schläfli. For n-D with $n \geq 5$, there are only three regular convex polytopes: the hypercube, cross polytope, and regular simplex, which are analogs of the cube, octahedron, and tetrahedron (Coxeter 1969; Wells 1991, p. 210).

Polytropic Differential Equation

LANE-EMDEN DIFFERENTIAL EQUATION

Poncelet Transform

PONCELET TRANSVERSE

Poncelet Transverse

Let a CIRCLE C_1 lie inside another CIRCLE C_2. From any point on C_2, draw a tangent to C_1 and extend it to C_2. From the point, draw another tangent, etc. For n tangents, the result is called an n-sided Poncelet transverse.

If, on the circle of circumscription there is one point of origin for which a four-sided Poncelet transverse is closed, then the four-sided transverse will also close for any other point of origin on the circle (Dörrie 1965).

Poncelet's Closure Theorem

PONCELET'S PORISM

Poncelet's Coaxal Theorem

If a CYCLIC QUADRILATERAL $ABCD$ is inscribed in a circle c_1 of a COAXAL SYSTEM such that one pair AC of connectors touches another circle c_2 of the system at P, then each pair of opposite connectors will touch a circle of the system (BD at P' on c_2, AB at Q on c_3, CD at Q' on c_3, DA at R on c_4, and CB at R' on c_4), and the six points of contact P, P', Q, Q', R, and R' will be COLLINEAR.

The general theorem states that if A_1, A_2, ..., A_n are any number of points taken in order on a CIRCLE of a give COAXAL SYSTEM so that A_1A_2, A_2A_3, ..., $A_{n-1}A_n$ touch respectively $n-1$ fixed circles X_1, X_2, ..., X_{n-1} of the system, then A_nA_1 must touch a fixed circle X_n of the system. Further, if A_1A_2, A_2A_3, ..., $A_{n-1}A_n$ touch respectively any $n-1$ of the circles X_1, X_2, ..., X_n, then A_nA_1 must touch the remaining CIRCLE.

See also COAXAL SYSTEM

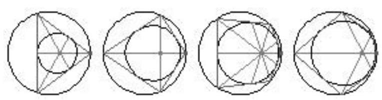
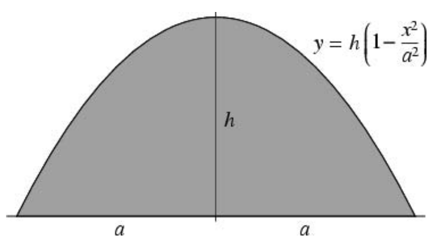
Poncelet's Continuity Principle



PERMANENCE OF MATHEMATICAL RELATIONS PRINCIPLE

Poncelet's Porism



If an n-sided PONCELET TRANSVERSE constructed for two given CONIC SECTIONS is closed for one point of

origin, it is closed for any position of the point of origin. Specifically, given one ELLIPSE inside another, if there exists one CIRCUMINSCRIBED (simultaneously inscribed in the outer and circumscribed on the inner) n-gon, then any point on the boundary of the outer ELLIPSE is the vertex of some CIRCUMINSCRIBED n-gon. If the conic is taken as a circle (Casey 1888, pp. 124–26) , then a polygon which has both an incenter and a circumcenter (and for which the transveRsals would therefore close) is called a BICENTRIC POLYGON.

For an even-sided polygon, the diagonals are concurrent at the LIMITING POINT of the two circles, whereas for an odd-sided polygon, the lines connecting the vertices to the opposite points of tangency are concurrent at the LIMITING POINT.

Inverting about either of the two LIMIT POINTS gives two concentric circles. However, the n-gonal sides become arcs of circles in the process, so this sort of simple INVERSION does not provide an automatic proof of the theorem (as happens in STEINER'S PORISM, for example).

Fuss (1792) derived formulas not only for the BICENTRIC QUADRILATERAL, but also the bicentric PENTAGON, HEXAGON, HEPTAGON, and OCTAGON, as did Steiner (Fuss 1792; Steiner 1827; Jacobi 1881; Dörrie 1965, p. 192). Chaundy (1923) exhibited porisms for $n = 3, 4, 5, 6, 7, 8, 9, 10, 12, 14, 16, 18, 20$, as well as erroneous expressions for several other values (Kerawala 1947). Richelot derived the expression for $n = 11$. In fact, there is a general analytic expression relating the CIRCUMRADIUS R, INRADIUS r, and offset between the CIRCUMCENTER and INCENTER d for a bicentric polygon. Given R, r, and d, define

$$a = \frac{1}{R + d} \tag{1}$$

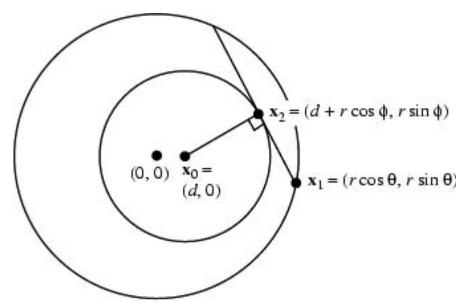
$$b = \frac{1}{R - d} \tag{2}$$

$$c = \frac{1}{r}. \tag{3}$$

Now let

$$\lambda = 1 + \frac{2c^2(a^2 - b^2)}{a^2(b^2 - c^2)} \tag{4}$$

$$\omega = \cosh^{-1}\lambda, \tag{5}$$



and define the MODULUS as

$$k^2 = 1 - e^{-2\omega}. \tag{6}$$

Then the condition for an n-gon to be bicentric is

$$\operatorname{sc}\left(\frac{K(k)}{n}, k\right) = \frac{c\sqrt{b^2 - a^2} + b\sqrt{c^2 - a^2}}{a(b + c)}, \tag{7}$$

where $\operatorname{sc}(x, k)$ is a JACOBI ELLIPTIC FUNCTION and $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND (Richelot 1830, Kerawala 1947). Kerawala (1947) was able to establish many porisms in simple explicit form without resorting to the use of elliptic functions.

For the two circles illustrated above, the tangent on the inner circle can be determined by solving

$$(\mathbf{x}_2 - \mathbf{x}_1)\cdot(\mathbf{x}_2 - \mathbf{x}_0) = 0, \tag{8}$$

where

$$\mathbf{x}_0 = \begin{bmatrix} d \\ 0 \end{bmatrix} \tag{9}$$

$$\mathbf{x}_1 = \begin{bmatrix} \cos\theta \\ \sin\theta \end{bmatrix} \tag{10}$$

$$\mathbf{x}_2 = \begin{bmatrix} d + r\cos\phi \\ r\sin\phi \end{bmatrix}, \tag{11}$$

r is the radius of the inner circle, x is the offset of the inner circle, θ is the given position on the outer circle, and ϕ is the angle around the inner circle at which the tangent occurs. Taking the DOT PRODUCT and simplifying gives

$$r + d\cos\phi - \cos(\phi - \theta) = 0. \tag{12}$$

When this is solved for ϕ, the point at which the extension of this line intersects the outer circle again

can be found using the standard equation of a CIRCLE-LINE INTERSECTION.

The degrees d_n of the algebraic equations relating a, b, and c for $n = 3, 4, ...$, are 1, 2, 3, 4, 6, 8, 9, 12, 15, 16, 21, 24, 24, 32, 36, ... (Sloane's A002348; Kerawala 1947). Let the PRIME FACTORIZATION of n be written as

$$n = 2^{\alpha_0} \prod_i p_i^{\alpha_i}, \tag{13}$$

then d_n in general is given by

$$d_n = \frac{4^{\alpha_0}}{8} \prod_i p_i^{2(\alpha_i - 1)}(p_i^2 - 1). \tag{14}$$

In the following expressions, write

$$e_0 \equiv a + b + c \tag{15}$$

$$e_1 \equiv -a + b + c \tag{16}$$

$$e_2 \equiv a - b + c \tag{17}$$

$$e_3 \equiv a + b - c \tag{18}$$

$$E_1 \equiv -a^2 + b^2 + c^2 \tag{19}$$

$$E_2 \equiv a^2 - b^2 + c^2 \tag{20}$$

$$E_3 \equiv a^2 + b^2 - c^2 \tag{21}$$

$$F_1 \equiv -E_2E_3 + E_3E_1 + E_1E_2 \tag{22}$$

$$F_2 \equiv E_2E_3 - E_3E_1 + E_1E_2 \tag{23}$$

$$F_3 \equiv E_2E_3 + E_3E_1 - E_1E_2 \tag{24}$$

$$F_0 \equiv E_2E_3 + E_3E_1 + E_1E_2 \equiv e_0e_1e_2e_3 \tag{25}$$

$$g_0 \equiv E_1E_2E_3 + 2abE_1E_2 + 2bcE_2E_3 + 2caE_3E_1 \tag{26}$$

$$g_1 \equiv E_1E_2E_3 - 2abE_1E_2 + 2bcE_1E_2 - 2caE_3E_1 \tag{27}$$

$$g_2 \equiv E_1E_2E_3 - 2abE_1E_2 - 2bcE_2E_3 + 2caE_3E_1 \tag{28}$$

$$g_3 \equiv E_1E_2E_3 + 2abE_1E_2 - 2bcE_2E_3 - 2caE_3E_1 \tag{29}$$

following Kerawala (1947), and

$$p = \frac{R + d}{r} \tag{30}$$

$$q = \frac{R - d}{r} \tag{31}$$

following Richelot (1830).

The equation for a bicentric triangle ($n = 3$), i.e., any triangle, may be variously written as

$$a + b = c \tag{32}$$

$$(R + d)^{-1} + (R - d)^{-1} = r^{-1} \tag{33}$$

$$\sqrt{R - d - r} + \sqrt{R + d - r} = \sqrt{2R} \tag{34}$$

$$(p - 1)(q - 1) = 1 \tag{35}$$

(Richelot 1830),

$$R^2 - 2Rr - d^2 = 0 \tag{36}$$

(Steiner 1827; F. Gabriel-Marie 1912, pp. 497–01; Kerawala 1947; Altshiller-Court 1957, pp. 85–7; Wells 1991). The latter is sometimes known as the EULER TRIANGLE FORMULA.

For a BICENTRIC QUADRILATERAL ($n = 4$), the radii and offset are connected by the equation

$$a^2 + b^2 = c^2, \tag{37}$$

(Kerawala 1947), which expands to

$$\frac{1}{(R-d)^2} + \frac{1}{(R+d)^2} = \frac{1}{r^2} \tag{38}$$

(Davis; Durége; Casey 1888, pp. 109–10; F. Gabriel-Marie 1912, pp. 321 and 814–16; Johnson 1929; Dörie 1965). This can also be written

$$(R^2 - d^2)^2 = 2r^2(R^2 + d^2), \tag{39}$$

$$(R + r + d)(R + r - d)(R - r + d)(R - r - d) = r^4 \tag{40}$$

(Steiner 1827), or

$$(p^2 - 1)(q^2 - 1) = 1 \tag{41}$$

(Richelot 1830).

The relationship for a bicentric PENTAGON ($n = 5$) is

$$r(R - d) = (R + d)\sqrt{(R - r + d)(R - r - d)}$$

$$+ (R + d)\sqrt{2R(R - r - d)} \tag{42}$$

(Steiner 1827) or

$$4p^2q^2(p - 1)(q - 1) = (p^2 + q^2 - p^2q^2)^2 \tag{43}$$

(Richelot 1830). A number of alternative forms are given by

$$(a + b)(b + c)(c + a) = a^3 + b^3 + c^3 \tag{44}$$

$$(a + b + c)^3 = 4(a^3 + b^3 + c^3) \tag{45}$$

$$(-a + b + c)(a - b + c)(a + b - c) + 4abc = 0 \tag{46}$$

$$\begin{vmatrix} e_0 & e_3 & e_2 \\ e_3 & e_0 & e_1 \\ e_2 & e_1 & e_0 \end{vmatrix} = 0 \tag{47}$$

$$a(-a^2 + b^2 + c^2) + b(a^2 - b^2 + c^2) + c(a^2 + b^2 - c^2)$$

$$+ 2abc = 0, \tag{48}$$

and

$$e_0^{-1}+e_1^{-1}+e_2^{-1}+e_3^{-1}=0 \quad (49)$$

(Kerawala 1947).

For $n=6$,

$$3(R^2-d^2)^4=4r^2(R^2+d^2)(R^2-d^2)+16r^4d^2R^2 \quad (50)$$

(Steiner 1827),

$$4p^2q^2(p^2-1)(q^2-1)=(p^2+q^2-p^2q^2)^2 \quad (51)$$

(Richelot 1830),

$$F_3=0, \quad (52)$$

or

$$E_1^{-1}+E_2^{-1}+E_3^{-1} \quad (53)$$

(Kerawala 1947).

For $n=7$,

$$g_3=0 \quad (54)$$

(Jacobi 1881, Kerawala 1947)

For $n=8$,

$$E_1^{-2}+E_2^{-2}=E_3^{-2} \quad (55)$$

(Kerawala 1947), which can also be written in the form

$$16p^4q^4(p^2-1)(q^2-1)=(p^2+q^2-p^2q^2)^4, \quad (56)$$

(Richelot 1830, Jacobi 1881). The equation given by Steiner (1827) contains (at least one) typographical error.

For $n=9$,

$$aF_2F_3+bF_3F_1-cF_1F_2=0. \quad (57)$$

for $n=10$,

$$16p^2q^2(p^2-1)(q^2-1)[p^4q^4-(p^2-q^2)^2]^2$$
$$=\{[p^4-(p^2q^2-q^2)^2]+[q^4-(p^2q^2-p^2)^2]^2$$
$$+[p^4q^4-(p^2-q^2)^2]\}^2 \quad (58)$$

(Richelot 1989).

For $n=12$,

$$64p^4q^4(p^2-1)(q^2-1)[p^4q^4-(p^2-q^2)^2]^2$$
$$=\{[p^4-(p^2q^2-q^2)^2]+[q^4-(p^2q^2-p^2)^2]^2$$
$$+[p^4q^4-(p^2-q^2)^2]\}^2 \quad (59)$$

(Richelot 1989).

For $n=14$,

$$g_1=0. \quad (60)$$

For $n=16$,

$$E_2^{-2}+E_3^{-2}=E_1^{-2}, \quad (61)$$

(Kerawala 1947) or

$$64p^4q^4(p^2-1)(q^2-1)\{p^4q^4-(p^2-q^2)^2]$$
$$\times(p^2+q^2-p^2q^2)\}^4$$
$$=\{[p^4-(p^2q^2-q^2)^2]+[q^4-(p^2q^2-p^2)^2]^2$$
$$+[p^4q^4-(p^2-q^2)^2]^2\}^4 \quad (62)$$

(Richelot 1830).

Weill (1878) gives an algorithm for finding approximate solutions (d, r, R) for porisms with even n. The following table gives the approximate relations for fixed $R \ll 1$.

n	d/R	r/R	error
6	$\frac{1}{2}$	$\frac{3}{4}$	$\frac{243}{128}R^8$
8	$\frac{1}{4}$	$\frac{15}{4}r$	$\frac{2955538440751415296}{6568408355712890625}R^{16}$
10	$\frac{1}{10}\sqrt{10}$	$\frac{9}{40}\sqrt{10}$

Poncelet-Steiner Theorem

All Euclidean GEOMETRIC CONSTRUCTIONS can be carried out with a STRAIGHTEDGE alone if, in addition, one is given the RADIUS of a single CIRCLE and its center. The theorem was suggested by Poncelet in 1822 and proved by Steiner in 1833. A construction using STRAIGHTEDGE alone is called a STEINER CONSTRUCTION.

Pontryagin Class

The ith Pontryagin class of a VECTOR BUNDLE is $(-1)^i$ times the ith CHERN CLASS of the complexification of the VECTOR BUNDLE. It is also in the $4i$th cohomology group of the base SPACE involved.

See also CHERN CLASS, STIEFEL-WHITNEY CLASS

Pontryagin Duality

Let G be a locally compact ABELIAN GROUP. Let G^* be the group of all homeomorphisms $G \to R/Z$, in the compact open topology. Then G^* is also a locally compact ABELIAN GROUP, where the asterisk defines a contravariant equivalence of the category of locally compact Abelian groups with itself. The natural mapping $G \to (G^*)^*$, sending g to G, where $G(f) = f(g)$, is an isomorphism and a HOMEOMORPHISM. Under this equivalence, compact groups are sent to discrete groups and vice versa.

See also ABELIAN GROUP, HOMEOMORPHISM

Pontryagin Maximum Principle

A result in CONTROL THEORY. Define

$$H(\psi, x, u) \equiv (\psi, f(x, u)) \equiv \sum_{a=0}^{n} \psi_a f^a(x, u).$$

Then in order for a control $u(t)$ and a trajectory $x(t)$ to be optimal, it is NECESSARY that there exist NONZERO absolutely continuous vector function $\psi(t) = (\psi_0(t), \psi_1(t), \ldots, \psi_n(t))$ corresponding to the functions $u(t)$ and $x(t)$ such that

1. The function $H(\psi(t), x(t), u)$ attains its maximum at the point $u = u(t)$ almost everywhere in the interval $t_0 \le t \le t_1$,

$$H(\psi(t), x(t), u(t)) = \max_{u \in U} H(\psi(t), x(t), u).$$

2. At the terminal time t_1, the relations $\psi_0(t_1) \le 0$ and $H(\psi(t_1), x(t_1), u(t_1)) = 0$ are satisfied.

See also CONTROL THEORY

Pontryagin Number

The Pontryagin number is defined in terms of the PONTRYAGIN CLASS of a MANIFOLD as follows. For any collection of PONTRYAGIN CLASSES such that their cup product has the same DIMENSION as the MANIFOLD, this cup product can be evaluated on the MANIFOLD's FUNDAMENTAL CLASS. The resulting number is called the Pontryagin number for that combination of Pontryagin classes. The most important aspect of Pontryagin numbers is that they are COBORDISM invariant. Together, Pontryagin and STIEFEL-WHITNEY NUMBERS determine an oriented manifold's oriented COBORDISM class.

See also CHERN NUMBER, STIEFEL-WHITNEY NUMBER

Ponzo's Illusion

The upper HORIZONTAL line segment in the above figure appears to be longer than the lower line segment despite the fact that both are the same length.

Pop

An action which removes a single element from the top of a QUEUE or STACK, turning the LIST (a_1, a_2, ..., a_n) into (a_2, ..., a_n) and yielding the element a_1.

See also PUSH, STACK

Population

The word population has a number of distinct but closely related meanings in statistics.

1. A finite and actually existing group of objects which, although possibly large, can be enumerated in theory (e.g., people living in the United States).
2. A generalization from experience which is indefinitely large (e.g., the total number of throws that might conceivably by made in unlimited time with a particular pair of dice). Any actual set of throws can then be regarded as a SAMPLE drawn from this practically infinite population.
3. A purely hypothetically population which can be completely described mathematically.

See also SAMPLE

Population Comparison

Let x_1 and x_2 be the number of successes in variates taken from two populations. Define

$$\hat{p}_1 \equiv \frac{x_1}{n_1} \qquad (1)$$

$$\hat{p}_2 \equiv \frac{x_2}{n_2} \quad (2)$$

The ESTIMATOR of the difference is then $\hat{p}_1 - \hat{p}_2$. Doing a Z-TRANSFORM,

$$z = \frac{(\hat{p}_1 - \hat{p}_2) - (p_1 - p_2)}{\sigma_{\hat{p}_1 - \hat{p}_2}}, \quad (3)$$

where

$$\sigma_{\hat{p}_1 - \hat{p}_2} \equiv \sqrt{\sigma_{\hat{p}_1}^2 - \sigma_{\hat{p}_2}^2}. \quad (4)$$

The STANDARD ERROR is

$$\mathrm{SE}_{\hat{p}_1 - \hat{p}_2} = \sqrt{\frac{\hat{p}_1(1 - \hat{p}_1)}{n_1} + \frac{\hat{p}_2(1 - \hat{p}_2)}{n_2}} \quad (5)$$

$$\mathrm{SE}_{\bar{x}_1 - \bar{x}_2} = \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}} \quad (6)$$

$$s_{\mathrm{pool}}^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}. \quad (7)$$

See also Z-TRANSFORM (POPULATION)

Population Growth

The differential equation describing exponential growth is

$$\frac{dN}{dt} = \frac{N}{\tau}. \quad (1)$$

This can be integrated directly

$$\int_{N_0}^{N} \frac{dN}{N} = \int_0^t \frac{dt}{\tau} \quad (2)$$

$$\ln\left(\frac{N}{N_0}\right) = \frac{t}{\tau}. \quad (3)$$

Exponentiating,

$$N(t) = N_0 e^{t/\tau}. \quad (4)$$

Defining $N(t = 1) = N_0 e^{\alpha}$ gives $\tau = 1/\alpha$ in (4), so

$$N(t) = N_0 e^{\alpha t}. \quad (5)$$

This equation is called the LAW OF GROWTH, and the quantity α in this equation is sometimes known as the MALTHUSIAN PARAMETER.

Consider a more complicated growth law

$$\frac{dN}{dt} = \left(\frac{\alpha t - 1}{t}\right) N, \quad (6)$$

where $\alpha > 1$ is a constant. This can also be integrated directly

$$\frac{dN}{N} = \left(\alpha - \frac{1}{t}\right) dt \quad (7)$$

$$\ln N = \alpha t - \ln t + C \quad (8)$$

$$N(t) = \frac{Ce^{\alpha t}}{t}. \quad (9)$$

Note that this expression blows up at $t = 0$. We are given the INITIAL CONDITION that $N(t = 1) = N_0 e^{\alpha}$, so $C = N_0$.

$$N(t) = N_0 \frac{e^{\alpha t}}{t}. \quad (10)$$

The t in the DENOMINATOR of (10) greatly suppresses the growth in the long run compared to the simple growth law.

The LOGISTIC GROWTH CURVE, defined by

$$\frac{dN}{dt} = \frac{r(K - N)}{N} \quad (11)$$

is another growth law which frequently arises in biology. It has a rather complicated solution for $N(t)$.

Pósa's Conjecture

Dirac (1952) proved that if the minimum VERTEX DEGREE $\delta(G) \geq n/2$ for a graph G on $n \geq 3$ nodes, then G contains a HAMILTONIAN CIRCUIT (Bollobás 1978, Komlós *et al.* 1998).

In 1962, Pósa conjectured that $G(V, E)$ contains a square of a HAMILTONIAN CIRCUIT if $\delta(G) \geq 2n/3$ (Erdos 1964, p. 159; Komlós *et al.* 1998), where a graph $G(V, E)$ contains the SQUARE of a HAMILTONIAN CIRCUIT if there is a HAMILTONIAN CIRCUIT $H = (x_1, x_2, \ldots, x_n, x_{n+1} = x_1)$ such that $(x_i, x_{i+2}) \in E(G)$, for $i = 1, 2, \ldots, n$.

Komlós *et al.* (1996) proved that there exists a natural number n_0 such that if a graph G has order $n \geq n_0$ and minimum degree at least $2n/3$, then G contains the square of a Hamiltonian circuit. This proved Pósa's conjecture (Erdos 1964) for sufficiently large n. Kierstead and Quintana (1998) proved Pósa's conjecture for graphs G containing a 4-clique K_4.

The conjecture was generalized by Seymour (1974) to state that if $\delta(G) \geq kn/(k+1)$, then G contains the kth power of a HAMILTONIAN CIRCUIT (Komlós *et al.* 1998).

Pósa's Theorem

There are several related theorems involving HAMILTONIAN CIRCUITS of graphs that are associated with Pósa.

Let G be a SIMPLE GRAPH with n VERTICES.

1. If, for every k in $1 \leq k < (n-1)/2$, the number of VERTICES of VERTEX DEGREE not exceeding k is less than k, and
2. If, for n ODD, the number of VERTICES with VERTEX DEGREE not exceeding $(n-1)/2$ is less than or equal to $(n-1)/2$,

then G contains a HAMILTONIAN CIRCUIT.

Kronk (1969) generalized this result as follows. Let G be a SIMPLE GRAPH with n VERTICES, and let $0 \leq k \leq n-2$. Then the following conditions are SUFFICIENT for G to be k-line Hamiltonian:

1. For all integers j with $k+1 \leq j < (n+k-1)/2$, the number of VERTICES of VERTEX DEGREE not exceeding j is less than $j-k$,
2. The number of points of degree not exceeding $(n+k-1)/2$ does not exceed $(n-k-1)/2$.

Pósa (1963) generalized a result of Dirac by proving that every FINITE SIMPLE GRAPH G with a sufficiently large valencies of all (or, in some cases, of ALMOST ALL) vertices and with a sufficiently large number of vertices satisfies one of the following conditions.

1. G has a Hamiltonian line containing all edges of given disjoint paths (Theorem 1),
2. G has a circuit with a "large" number of vertices (Theorems 2 and 3), or
3. G has a "small" number of disjoint circuits containing all vertices of the graph (Theorems 4 and 5).

Position Four-Vector

The contravariant four-vector arising in special and general relativity,

$$x^\mu = \begin{bmatrix} x^0 \\ x^1 \\ x^2 \\ x^3 \end{bmatrix} \equiv \begin{bmatrix} ct \\ x \\ y \\ z \end{bmatrix},$$

where c is the speed of light and t is time. Multiplication of two four-vectors gives the spacetime interval

$$\begin{aligned} I = g_{\mu\nu}x^\mu x^\nu &= (x^0)^2 - (x^1)^2 - (x^2)^2 - (x^3)^2 \\ &= (ct)^2 - (x^1)^2 - (x^2)^2 - (x^3)^2 \end{aligned}$$

See also Four-Vector, Lorentz Transformation, Quaternion

Position Vector

Radius Vector

Positive

A quantity $x > 0$, which may be written with an explicit plus sign for emphasis, $+x$.

See also Negative, Nonnegative, Plus Sign, Zero

Positive Definite Function

A positive definite function f on a group G is a function for which the matrix $\{f(x_i x_j^{-1})\}$ is always positive semidefinite Hermitian.

References

Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537–49, 1996.

Positive Definite Matrix

A Hermitian matrix $\mathbf{A}$ is called positive definite if

$$(\mathbf{Av}) \cdot \mathbf{v} > 0 \qquad (1)$$

for all vectors $\mathbf{v} \neq 0$. This is equivalent to the requirement that all eigenvalues be positive, and to the requirement that the determinants associated with *all* upper-left submatrices are positive.

The determinant of a positive definite matrix is positive, but the converse is not necessarily true (i.e., a matrix with a positive determinant is not necessarily positive definite).

The numbers of positive definite $n \times n$ matrices of given types are summarized in the following table. For example, the three positive definite 2×2 (0,1)-

MATRICES are

$$\begin{bmatrix}1 & 0\\0 & 1\end{bmatrix}, \begin{bmatrix}1 & 0\\1 & 1\end{bmatrix}, \begin{bmatrix}1 & 1\\0 & 1\end{bmatrix}, \quad (2)$$

all of which have eigenvalue 1 with degeneracy of two.

(0, 1)-matrix	A000000	0, 3, 25, 543, ...
(−1, 0, 1)-matrix	A000000	0, 5, 133, ...

A REAL SYMMETRIC MATRIX A is positive definite IFF there exists a REAL nonsingular MATRIX M such that

$$\mathsf{A} = \mathsf{M}\mathsf{M}^{\mathrm{T}} \quad (3)$$

where M^{T} is the TRANSPOSE. A 2×2 SYMMETRIC MATRIX

$$\begin{bmatrix}a & b\\b & c\end{bmatrix} \quad (4)$$

is positive definite if

$$av_1^2 + 2bv_1v_2 + cv_2^2 > 0 \quad (5)$$

for all $\mathbf{v} = (v_1, v_2) \neq 0$.

A HERMITIAN MATRIX A is positive definite if

1. $a_{ii} > 0$ for all i,
2. $a_{ii}a_{ij} > |a_{ij}|^2$ for $i \neq j$,
3. The element of largest modulus lies on the leading diagonal,
4. $\det(\mathsf{A}) > 0$.

Positive Definite Quadratic Form

A QUADRATIC FORM $Q(\mathbf{x})$ is said to be positive definite if $Q(\mathbf{x}) > 0$ for $\mathbf{x} \neq 0$. A REAL QUADRATIC FORM in n variables is positive definite IFF its canonical form is

$$Q(\mathbf{z}) = z_1^2 + z_2^2 + \ldots + z_n^2. \quad (1)$$

A BINARY QUADRATIC FORM

$$F(x, y) = a_{11}x^2 + 2a_{12}xy + a_{22}y^2 \quad (2)$$

of two REAL variables is positive definite if it is > 0 for any $(x, y) \neq (0, 0)$, therefore if $a_{11} > 0$ and the DISCRIMINANT $a \equiv a_{11}a_{22} - a_{12}^2 > 0$. A BINARY QUADRATIC FORM is positive definite if there exist NONZERO x and y such that

$$(ax^2 + 2bxy + cy^2)^2 \leq \tfrac{4}{3}|ac - b^2| \quad (3)$$

(Le Lionnais 1983).

A QUADRATIC FORM $(\mathbf{x}, \mathsf{A}\mathbf{x})$ is positive definite IFF every EIGENVALUE of A is POSITIVE. A QUADRATIC FORM $Q = (\mathbf{x}, \mathsf{A}\mathbf{x})$ with A a HERMITIAN MATRIX is positive definite if all the principal minors in the top-left corner of A are POSITIVE, in other words

$$a_{11} > 0 \quad (4)$$

$$\begin{vmatrix}a_{11} & a_{12}\\a_{21} & a_{22}\end{vmatrix} > 0 \quad (5)$$

$$\begin{vmatrix}a_{11} & a_{12} & a_{13}\\a_{21} & a_{22} & a_{23}\\a_{31} & a_{32} & a_{33}\end{vmatrix} > 0 \quad (6)$$

Positive Definite Sequence

This entry contributed by RONALD M. AARTS

A sequence $\{\mu_n\}_{n=0}^{\infty}$ is positive definite if the moment of every nonnegative polynomial which is not identically zero is greater than zero (Widder 1941, p. 132). Here, the moment of a polynomial

$$P_n(x) = \sum_{m=0}^{n} a_m x^m$$

with respect to the sequence $\{\mu_n\}_{n=0}^{\infty}$ is defined as

$$M(P_n(x)) = \sum_{m=0}^{n} a_m \mu_m$$

(Widder 1941, p. 102).

References

Widder, D. V. *The Laplace Transform.* Princeton, NJ: Princeton University Press, 1941.

Positive Definite Tensor

A TENSOR g whose discriminant satisfies

$$g \equiv g_{11}g_{22} - g_{12}^2 > 0.$$

Positive Integer

The positive integers are the numbers 1, 2, 3, ..., sometimes called the counting numbers or natural numbers.

See also $\mathbb{Z}+$

Positive Measure

A positive measure is a MEASURE which is a function from the measurable sets of a MEASURE SPACE to the nonnegative real numbers. Sometimes, this is what is meant by MEASURE, while "positive" is used to distinguish it from an arbitrary COMPLEX MEASURE.

See also COMPLEX MEASURE, JORDAN MEASURE DECOMPOSITION, LEBESGUE INTEGRAL, MEASURE, MEASURE SPACE, POLAR REPRESENTATION (MEASURE)

Positive Semidefinite Matrix

A positive semidefinite matrix is a HERMITIAN MATRIX all of whose EIGENVALUES are nonnegative.

See also NEGATIVE DEFINITE MATRIX, NEGATIVE SEMIDEFINITE MATRIX, POSITIVE DEFINITE MATRIX

Postage Stamp Problem

Consider a SET $A_k = \{a_1, a_2, \ldots a_k\}$ of INTEGER denomination postage stamps with $1 = a_1 < a_2 \ldots < a_k$. Suppose they are to be used on an envelope with room for no more than h stamps. The postage stamp problem then consists of determining the smallest INTEGER $N(h, A_k)$ which cannot be represented by a LINEAR COMBINATION $\Sigma_{i=1}^k x_i a_i$ with $x_i \geq 0$ and $\Sigma_{i=1}^k x_i < h$. Exact solutions exist for arbitrary A_k for $k=2$ and 3. The $k=2$ solution is

$$n(h, A_2) = (h + 3 - a_2)a_2 - 2$$

for $h \geq a_2 - 2$. The general problem consists of finding

$$n(h,\ k) = \max_{A_k}\ n(h, A_k).$$

It is known that

$$n(h,\ 2) = \left\lfloor \tfrac{1}{4}(h^2 + 6h + 1) \right\rfloor,$$

(Stöhr 1955, Guy 1994), where $\lfloor x \rfloor$ is the FLOOR FUNCTION, the first few values of which are 2, 4, 7, 10, 14, 18, 23, 28, 34, 40, ... (Sloane's A014616).

Pothenot Problem

SNELLIUS-POTHENOT PROBLEM

Poulet Number

A FERMAT PSEUDOPRIME to base 2, denoted psp(2), i.e., a COMPOSITE ODD INTEGER n such that

$$2^{n-1} \equiv 1 \pmod{n}.$$

The first few Poulet numbers are 341, 561, 645, 1105, 1387, ... (Sloane's A001567). Pomerance *et al.* (1980) computed all 21,853 Poulet numbers less than 25×10^9. The numbers less than 10^2, 10^3, ..., are 0, 3, 22, 78, 245, ... (Sloane's A055550).

Pomerance has shown that the number of Poulet numbers less than x for sufficiently large x satisfy

$$\exp\left[(\ln x)^{5/14}\right] < P_2(x) < x \exp\left(-\frac{\ln x \ln \ln \ln x}{2 \ln \ln x}\right)$$

(Guy 1994).

A Poulet number all of whose DIVISORS d satisfy $d | 2^d - 2$ is called a SUPER-POULET NUMBER. There are an infinite number of Poulet numbers which are not SUPER-POULET NUMBERS. Shanks (1993) calls *any* integer satisfying $2^{n-1} \equiv 1 \pmod{n}$ (i.e., not limited to ODD composite numbers) a FERMATIAN.

See also FERMAT PSEUDOPRIME, PSEUDOPRIME, ROTKIEWICZ THEOREM, SUPER-POULET NUMBER

Power

The exponent to which a given quantity is raised is known as its POWER. The expression x^a is therefore known as "x to the ath POWER." The power may be an integer, REAL NUMBER, or COMPLEX NUMBER. However, the power of a real number to a non-integer power is not necessarily itself a real number. For example, $x^{1/2}$ is real only for $x \geq 0$. The rules for combining quantities containing powers are called the EXPONENT LAWS.

While the simple equation

$$a^x = x$$

cannot be solved for x using traditional elementary functions, the solution can be given in terms of LAMBERT'S W-FUNCTION as

$$x = -\frac{W(-\ln a)}{\ln a},$$

where $\ln a$ is the NATURAL LOGARITHM of a.

Special names given to various powers are listed in the following table.

Power	Name
1/2	SQUARE ROOT
1/3	CUBE ROOT
2	SQUARED
3	CUBED

The largest powers p which numbers $n = 1, 2, 3, \ldots$ can be represented in the form $n = a^p$ are 1, 1, 1, 2, 1, 1, 1, 3, 2, 1, ... (Sloane's A052409), with corresponding values of a given by 1, 2, 3, 2, 5, 6, 7, 2, 3, 10, ... (Sloane's A052410).

The POWER SUM of the first n POSITIVE INTEGERS is given by FAULHABER'S FORMULA,

$$\sum_{k=1}^{n} k^p = \frac{1}{p+1} \sum_{k=1}^{p+1} (-1)^{\delta_{kp}} \binom{p+1}{k} B_{p+1-k} n^k,$$

where δ_{kp} is the KRONECKER DELTA, $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, and B_k is a BERNOULLI NUMBER.

Let s_n be the largest INTEGER that is not the SUM of distinct nth powers of POSITIVE INTEGERS (Guy 1994). The first few values for $n = 2, 3, \ldots$ are 128, 12758, 5134240, 67898771, ... (Sloane's A001661).

CATALAN'S CONJECTURE states that 8 and 9 (2^3 and 3^2) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. This CONJECTURE has not yet been proved or refuted, although R. Tijdeman has proved that there can be only a finite number of exceptions should the CONJECTURE not hold. It is also known that 8 and 9 are the only consecutive CUBIC and SQUARE NUMBERS (in either order). Hyyro and Makowski proved that there do not exist three consecutive POWERS (Ribenboim 1996).

Very few numbers OF THE FORM $n^p \pm 1$ are PRIME (where composite powers $p = kb$ need not be considered, since $n(kb) \pm 1 = (n^k)^b \pm 1$). The only PRIME NUMBERS OF THE FORM $n^p - 1$ for $n \leq 100$ and PRIME $2 \leq p \leq 10$ correspond to $n = 2$, i.e., $2^2 - 1 = 3$, $2^3 - 1 = 7$, $2^5 - 1 = 31$, ... The only PRIME NUMBERS of the form $n^p + 1$ for $n \leq 100$ and PRIME $2 \leq p \leq 10$ correspond to $p = 2$ with $n = 1, 2, 4, 6, 10, 14, 16, 20, 24, 26, \ldots$ (Sloane's A005574).

There are no nontrivial solutions to the equation

$$1^n + 2^n + \ldots + m^n = (m+1)^n$$

for $m \leq 10^{2{,}000{,}000}$ (Guy 1994, p. 153).

Power (Circle)

The POWER of a fixed point A with respect to a CIRCLE of RADIUS r and center O is defined by the product

$$p \equiv AP \times AQ, \tag{1}$$

where P and Q are the intersections of a line through A with the circle. The term "power" was first used in this way by Jacob Steiner (Steiner 1826; Coxeter and Greitzer 1967, p. 30). Amazingly, p (sometimes written k^2) is *independent* of the choice of the line APQ (Coxeter 1969, p. 81).

Now consider a point P not necessarily on the circumference of the circle. If $d = OP$ is the distance between P and the circle's center O, then the power of

the point P relative to the circle is

$$p = d^2 - r^2. \quad (2)$$

If P is outside the CIRCLE, its power is POSITIVE and equal to the square of the length of the segment PQ from P to the tangent Q to the CIRCLE through P,

$$p = PQ^2 = d^2 - r^2. \quad (3)$$

If OP lies along the X-AXIS, then the angle θ around the circle at which Q lies is given by solving

$$\left[(d - \cos\theta)^2 + \sin^2\theta\right] + 1 = d^2 \quad (4)$$

for θ, giving

$$\theta = \pm\sec^{-1} d \quad (5)$$

for coordinates

$$(x, y) = r\left(\pm\frac{1}{d}, \sqrt{\frac{d^2 - 1}{d^2}}\right). \quad (6)$$

The points P and P' are INVERSE POINTS, also called polar reciprocals, with respect to the INVERSION CIRCLE if

$$OP \cdot OP' = OQ^2 = r^2 \quad (7)$$

(Wenninger 1983, p. 2).
If P is inside the CIRCLE, then the power is NEGATIVE and equal to the product of the DIAMETERS through P.

The LOCUS of points having POWER k with regard to a fixed CIRCLE of RADIUS r is a CONCENTRIC CIRCLE of RADIUS $\sqrt{r^2 + k}$. The CHORDAL THEOREM states that the LOCUS of points having equal POWER with respect to two given nonconcentric CIRCLES is a line called the RADICAL LINE (or CHORDAL; Dörrie 1965).

See also CHORDAL THEOREM, COAXAL CIRCLES, INVERSE POINTS, INVERSION CIRCLE, INVERSION RADIUS, INVERSIVE DISTANCE, RADICAL LINE

Power (Statistics)

The probability of getting a positive result for a given test which should produce a positive result.

See also PREDICTIVE VALUE, SENSITIVITY, SPECIFICITY, STATISTICAL TEST

Power (Triangle)

The total power of a TRIANGLE is defined by

$$P \equiv \tfrac{1}{2}(a_1^2 + a_2^2 + a_3^2), \quad (1)$$

where a_i are the side lengths, and the "partial power" is defined by

$$p_1 = \tfrac{1}{2}(a_2^2 + a_3^2 - a_1^2). \quad (2)$$

Then

$$p_1 = a_2 a_3 \cos\alpha_1 \quad (3)$$

$$P = p_1 + p_2 + p_3 \quad (4)$$

$$P^2 + p_1^2 + p_2^2 + p_3^2 = a_1^4 + a_2^4 + a_3^4 \quad (5)$$

$$\Delta = \tfrac{1}{2}\sqrt{p_2 p_3 + p_3 p_1 + p_1 p_2} \quad (6)$$

$$p_1 = \overline{A_1 H_2} \cdot \overline{A_1 A_3} \quad (7)$$

$$\frac{a_1 p_1}{\cos\alpha_1} = a_1 a_2 a_3 = 4\Delta R \quad (8)$$

$$p_1 \tan\alpha_1 = p_2 \tan\alpha_2 = p_3 \tan\alpha_3, \quad (9)$$

where Δ is the AREA of the TRIANGLE and H_i are the FEET of the ALTITUDES. finally, if a side of the TRIANGLE and the value of any partial power are given, then the LOCUS of the third VERTEX is a CIRCLE or straight line.

Power Polynomial

The power polynomials x^n are an associated SHEFFER SEQUENCE with

$$f(t) = t, \tag{1}$$

giving GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{x^k}{k!} t^k = e^x t \tag{2}$$

and BINOMIAL IDENTITY

$$(x+y)^n = \sum_{k=0}^{n} \binom{n}{k} x^k y^{n-k}. \tag{3}$$

See also SHEFFER SEQUENCE

Power Series

A power series in a variable z is an infinite SUM OF THE FORM

$$\sum_{n}^{\infty} a_i z^i, \tag{1}$$

where $n \geq 0$ and a_i are INTEGERS, REAL NUMBERS, COMPLEX NUMBERS, or any other quantities of a given type.

A CONJECTURE of Pólya is that if a FUNCTION has a power series with INTEGER COEFFICIENTS and RADIUS OF CONVERGENCE 1, then either the FUNCTION is RATIONAL or the UNIT CIRCLE is a natural boundary.

A generalized POWER sum $a(h)$ for $h = 0, 1, \ldots$ is given by

$$a(h) = \sum_{i=1}^{m} A_i(h) \alpha_i^h, \tag{2}$$

with distinct NONZERO ROOTS α_i, COEFFICIENTS $A_i(h)$ which are POLYNOMIALS of degree $n_i - 1$ for POSITIVE INTEGERS n_i, and $i \in [1, m]$. The generalized POWER sum has order

$$n \equiv \sum_{i=m}^{m} n_i. \tag{3}$$

For any power series, one of the following is true:

1. The series converges only for $x = 0$.
2. The series converges absolutely for all x.
3. The series converges absolutely for all x in some finite open interval $(-R, R)$ and diverges if $x < -R$ or $x > R$. At the points $x = R$ and $x = -R$, the series may converge absolutely, converge conditionally, or diverge.

To determine the interval of convergence, apply the RATIO TEST for ABSOLUTE CONVERGENCE and solve for x. A power series may be differentiated or integrated within the interval of convergence. Convergent power series may be multiplied and divided (if there is no division by zero).

$$\sum_{k=1}^{\infty} k^{-p} \quad (4)$$

CONVERGES if $p > 1$ and DIVERGES if $0 < p \leq 1$.

Power Set

Given a SET S, the power set of S is the SET of all SUBSETS of S. The order of a POWER set of a SET of order n is 2^n. Power sets are larger than the SETS associated with them. The power set of S is variously denoted 2^S or $\mathscr{P}(S)$.

The power set of a given set s can be found using `Subsets[s]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``). A concise implementation in *Mathematica* is given by

```
PowerSet[s_List] :=    Distribute[Thread[{{},
List /@ s}, List, {2, 2}],
    List, List, List, Join]
```

See also SET, SUBSET

Power Spectrum

For a given signal, the power spectrum gives a plot of the portion of a signal's power (energy per unit time) falling within given frequency bins. The most common way of generating a power spectrum is by using a FOURIER TRANSFORM, but other techniques such as the MAXIMUM ENTROPY METHOD can also be used.

Power Sum

An analytic solution for a SUM of POWERS of integers is

$$S_p(n) = \sum_{k=1}^{n} k^p = \zeta(-p) - \zeta(-p,\ 1+n) = H_n^{(-p)}, \quad (1)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION, $\zeta(z;\ a)$ is the HURWITZ ZETA FUNCTION, and $H_n^{(k)}$ is a generalized HARMONIC NUMBER. For the special case of p a POSITIVE INTEGER, FAULHABER'S FORMULA gives the SUM explicitly as

$$S_p(n) = \frac{1}{p+1} \sum_{k=1}^{p+1} (-1)^{\delta_{kp}} \binom{p+1}{k} B_{p+1-k} n^k, \quad (2)$$

where δ_{kp} is the KRONECKER DELTA, $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, and B_k is a BERNOULLI NUMBER. Written explicitly in terms of a sum of POWERS,

$$S_p(n) = \frac{B_k p!}{k!(p-k+1)!}\, n^{p-k+1}. \quad (3)$$

It is also true that the COEFFICIENTS of the terms in such an expansion sum to 1, as stated by Bernoulli without proof (Boyer 1943).

Computing the sums for $p = 1, ..., 10$ gives

$$\sum_{k=1}^{n} k = \tfrac{1}{2}(n^2 + n) \quad (4)$$

$$\sum_{k=1}^{n} k^2 = \tfrac{1}{6}(2n^3 + 3n^3 + n) \quad (5)$$

$$\sum_{k=1}^{n} k^3 = \tfrac{1}{4}(n^4 + 2n^3 + n^2) \quad (6)$$

$$\sum_{k=1}^{n} k^4 = \tfrac{1}{30}(6n^5 + 15n^4 + 10n^3 - n) \quad (7)$$

$$\sum_{k=1}^{n} k^5 = \tfrac{1}{12}(2n^6 + 6n^5 + 5n^4 - n^2) \quad (8)$$

$$\sum_{k=1}^{n} k^6 = \tfrac{1}{42}(6n^7 + 21n^6 + 21n^5 - 7n^3 + n) \quad (9)$$

$$\sum_{k=1}^{n} k^7 = \tfrac{1}{24}(3n^8 + 12n^7 + 14n^6 - 7n^4 + 2n^2) \quad (10)$$

$$\sum_{k=1}^{n} k^8 = \tfrac{1}{90}(10n^9 + 45n^8 + 60n^7 - 42n^5 + 20n^3 - 3n) \quad (11)$$

$$\sum_{k=1}^{n} k^9 = \tfrac{1}{20}\left(2n^{10} + 10n^9 + 15n^8 - 14n^6 + 10n^4 - 3n^2\right) \quad (12)$$

$$\sum_{k=1}^{n} k^{10} = \tfrac{1}{66}(6n^{11} + 33n^{10} + 55n^9 - 66n^7 + 66n^5 - 33n^3 + 5n). \quad (13)$$

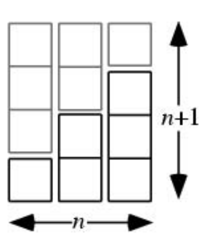
$$\sum_{k=1}^{n} k = \tfrac{1}{2}\, n(n+1) \quad (14)$$

$$\sum_{k=1}^{n} k^2 = \tfrac{1}{6}\, n(n+1)(2n+1) \quad (15)$$

$$\sum_{k=1}^{n} k^3 = \tfrac{1}{4}\, n^2(n+1)^2 \quad (16)$$

$$\sum_{k=1}^{n} k^4 = \tfrac{1}{30}\, n(n+1)(2n+1)\left(3n^2 + 3n - 1\right) \quad (17)$$

$$\sum_{k=1}^{n} k^5 = \tfrac{1}{12}\, n^2(n+1)^2(2n^2 + 2n - 1) \quad (18)$$



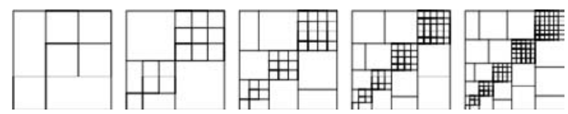
$$\sum_{k=1}^{n} k^6 = \tfrac{1}{42}\, n(n+1)(2n+1)\left(3n^4 + 6n^3 - 3n + 1\right) \quad (19)$$

$$\sum_{k=1}^{n} k^7 = \tfrac{1}{24}\, n^2(n+1)^2\left(3n^4 + 6n^3 - n^2 - 4n + 2\right) \quad (20)$$

$$\sum_{k=1}^{n} k^8 = \tfrac{1}{90}\, n(n+1)(2n+1) \times \left(5n^6 + 15n^5 + 5n^4 - 15n^3 - n^2 + 9n - 3\right) \quad (21)$$

$$\sum_{k=1}^{n} k^9 = \tfrac{1}{20}\, n^2(n+1)^2\left(n^2 + n - 1\right) \times \left(2n^4 + 4n^3 - n^2 - 3n + 3\right) \quad (22)$$

$$\sum_{k=1}^{n} k^{10} = \tfrac{1}{60}\, n(n+1)(2n+1)\left(n^2 + n - 1\right) \times\left(3n^6 + 9n^5 + 2n^4 - 11n^3 + 10n - 5\right). \quad (23)$$



A simple graphical proof of the special case of $S_1(n) = n(n+1)/2$ can also be given by constructing a sequence of stacks of boxes, each 1 unit across and k units high, where $k = 1, 2, ..., n$. Now add a rotated copy on top, as in the above figure. Note that the resulting figure has WIDTH n and HEIGHT $n+1$, and so has AREA $n(n+1)$. The desired sum is half this, so the AREA of the boxes in the sum is $n(n+1)/2$. Since the boxes are of unit width, this is also the value of the sum.

The sum $S_1(n) = n(n+1)/2$ can also be computed using the first EULER-MACLAURIN INTEGRATION FORMULA

$$\sum_{k=1}^{n} f(k) = \int_1^n f(x)\, dx + \tfrac{1}{2} f(1) + \tfrac{1}{2} f(n) + \tfrac{1}{2!} B_2[f'(n) - f'(1)] + \ldots \quad (24)$$

with $f(k) = k$. Then

$$\sum_{k=1}^{n} k = \int_1^n x\, dx + \tfrac{1}{2} \cdot 1 + \tfrac{1}{2} \cdot n + \tfrac{1}{6}(1-1) + \ldots$$
$$= \tfrac{1}{2}\left(n^2 - 1\right) - \tfrac{1}{2} + h + \tfrac{1}{2}\, n = \tfrac{1}{2}\, n(n+1). \quad (25)$$

The surprising identity

$$S_3(n) = \sum_{k=1}^{n} k^3 = \left(\sum_{k=1}^{n} k\right)^2, \quad (26)$$

known as NICOMACHUS'S THEOREM, can also be illustrated graphically (Wells 1991, pp. 198–99).

Schultz (1980) showed that the sum $S_k(n)$ can be found by writing

$$S_k(n) = A_{k+1} n^{k+1} + \ldots + A_1 n \quad (27)$$

and solving the system of $k+1$ equations

$$\sum_{i=j+1}^{k+1} (-1)^{i-j+1} \binom{i}{j} A_i = 0 \quad (28)$$

for $0 \le j \le k$ (Guo and Qi 1999).

$S_i(n)$ is related to the BINOMIAL THEOREM by

$$(1+n)^{k+1} = 1 + \sum_{i=0}^{k} \binom{k+1}{i} S_i(n) \quad (29)$$

(Guo and Qi 1999).

Power Tower

N.B. A detailed online essay by S. Finch was the starting point for this entry.

The power tower of order k is defined as

$$a \uparrow\uparrow k \equiv \underbrace{a^{a^{\cdot^{\cdot^{\cdot^{a}}}}}}_{k}, \qquad (1)$$

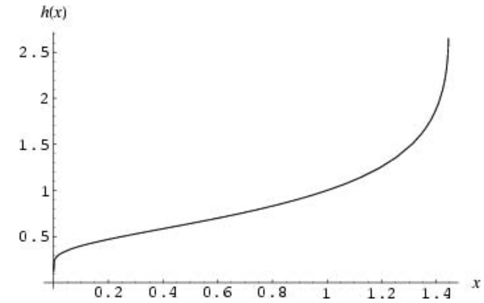
where $\uparrow$ is Knuth's (1976) ARROW NOTATION, which in turn is defined by

$$a \uparrow^k n = a \uparrow^{k-1} \left[a \uparrow^k (n-1)\right]. \qquad (2)$$

Rucker (1995, p. 74) uses the notation

$$^{k}a \equiv \underbrace{a^{a^{\cdot^{\cdot^{\cdot^{a}}}}}}_{n}, \qquad (3)$$

and refers to this operation as "tetration." A power tower can be implemented in *Mathematica* as



```
PowerTower[a_, k_] := Fold[Power[a, #] &, 1,
Table[a, {k}]]
```

The following table gives values of $\underbrace{a^{a^{\cdot^{\cdot^{\cdot^{a}}}}}}_{n}$ for $a = 1, 2, \ldots$ for small n.

n	$\underbrace{a^{a^{\cdot^{\cdot^{\cdot^{a}}}}}}_{n}$
1	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
2	1, 4, 27, 256, 3125, 46656, ...
3	1, 16, 7.63×10^{12}, 1.34×10^{154}, ...
4	1, 65536, ...

The following table gives $\underbrace{a^{a^{\cdot^{\cdot^{\cdot^{a}}}}}}_{n}$ for $n = 1, 2, \ldots$ for small a.

a	$\underbrace{a^{a^{\cdot^{\cdot^{\cdot^{a}}}}}}_{n}$
1	1, 1, 1, 1, 1, 1, ...
2	2, 4, 16, 65536, 2.00×10^{19728}, ...
3	3, 27, 7.63×10^{12}, ...
4	4, 256, 1.34×10^{154}, ...

The value of the infinite power tower $h(x) = x \uparrow\uparrow \infty = x^{x^{\cdot^{\cdot^{\cdot}}}}$, where x^{x^x} is an abbreviation for $x^{(x^x)}$, can be computed analytically by writing

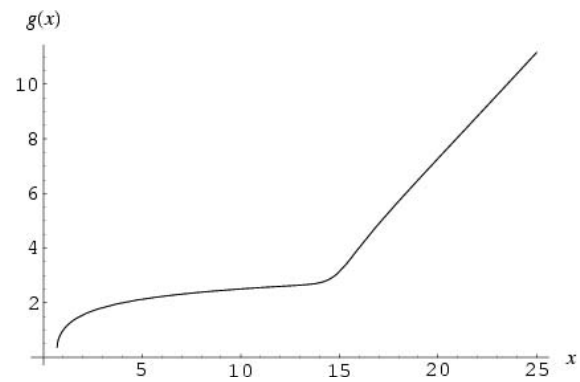
$$x^{x^{\cdot^{\cdot^{\cdot}}}} = h(x) \qquad (4)$$

taking the logarithm of both sides and plugging back in to obtain

$$x^{x^{\cdot^{\cdot^{\cdot}}}} \ln x = h(x) \ln x = \ln[h(x)]. \qquad (5)$$

Solving for $h(x)$ gives

$$h(x) = -\frac{W(-\ln x)}{\ln x}, \qquad (6)$$



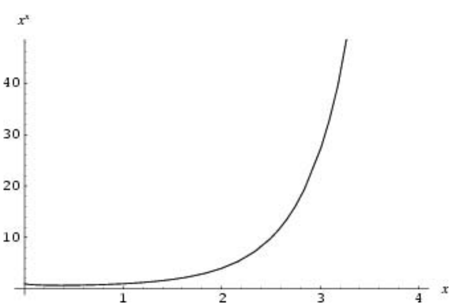
where $W(x)$ is LAMBERT'S W-FUNCTION (Corless *et al.*). $h(x)$ converges IFF $e^{-e} \leq x \leq e^{1/e}$ $(0.0659 \leq x \leq 1.4446)$, as shown by Euler (1783) and Eisenstein (1844) (Le Lionnais 1983, Wells 1986, p. 35).

Knoebel (1981) gave the following series for $h(z)$

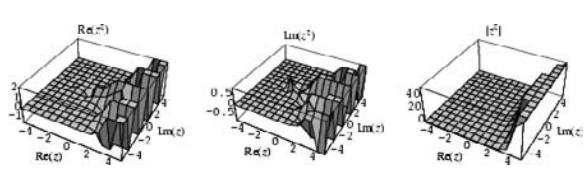
$$h(z) = 1 + \ln x + \frac{3^2(\ln z)^2}{3!} + \frac{4^3(\ln z)^3}{4!} + \ldots \qquad (7)$$

(Vardi 1991), and a CONTINUED FRACTION due to Khovanskii (1963) is

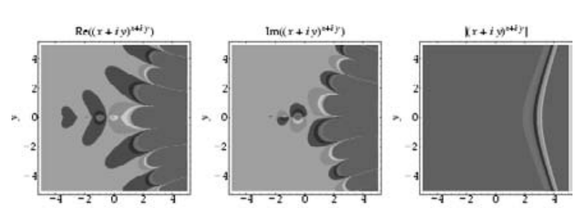
$$x^{1/x} = 1 + \cfrac{2(x-1)}{x^2+1-\cfrac{(x^2-1)(x-1)^2}{3x(x+1)\cfrac{(4x^2-1)(x-1)^2}{5x(x+1)-\cfrac{(9x^2-1)(x-1)^2}{7x(x+1)-\ldots}}}}. \quad (8)$$



The related function



$$g(x) = x^{(1/x)^{(1/x)^{\cdot^{\cdot^{\cdot}}}}} \quad (9)$$



converges only for $x \geq e^{-1/e}$, that is, $x \geq 0.692$. The value it converges to is the inverse of x^x which, for $x < e^e$ (i.e., $x < 15.154$), is given by

$$g(x) = \frac{\ln x}{W(\ln x)} \quad (10)$$

for $e^{-1/e} \leq x \leq e^e$.

The function x^x is plotted above along the real line and in the complex plane. It has a minimum where

$$\frac{d}{dx} x^x = x^x(1 + \ln x) = 0, \quad (11)$$

which has solution $x = 1/e$. At this point, the function takes on the value $e^{-1/e}$.

Some interesting related integrals are

$$\int_0^1 x^x \, dx = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^n} = 0.7834305107\ldots \quad (12)$$

$$\int_0^1 x^{-x} \, dx = \sum_{n=1}^{\infty} \frac{1}{n^n} = 1.2912859971\ldots \quad (13)$$

(Spiegel 1968, Abramowitz and Stegun 1972).

Powerfree

A POSITIVE INTEGER n is kth powerfree if there is no number d such that $d^k|n$ (d^k divides n), i.e., there are no kth powers or higher in the PRIME FACTORIZATION of n. A number which is free of all powers is therefore SQUAREFREE.

See also BIQUADRATEFREE, CUBEFREE, PRIME NUMBER, SQUAREFREE

References

Baake, M.; Moody, R. V.; and Pleasants, P. A. B. Diffraction from Visible Lattice Points and kth Power Free Integers. 19 Jun 1999. http://xxx.lanl.gov/abs/math.MG/9906132/.

Powerful Number

An INTEGER m such that if $p|m$, then $p^2|m$, is called a powerful number. The first few are 1, 4, 8, 9, 16, 25, 27, 32, 36, 49, ... (Sloane's A001694). Powerful numbers are always OF THE FORM a^2b^3 for a, $b \geq 1$.

Not every NATURAL NUMBER is the sum of two powerful numbers, but Heath-Brown (1988) has shown that every sufficiently large NATURAL NUMBER is the sum of at most three powerful numbers. There are infinitely many pairs of consecutive powerful numbers, but Erdos has conjectured that there do not exist three consecutive powerful numbers. The CONJECTURE that there are no powerful number triples implies that there are infinitely many Wieferich primes (Granville 1986, Vardi 1991).

A separate usage of the term powerful number is for numbers which are the sums of *any* positive powers of their digits (not necessarily the same for each digit). The first few are 1, 2, 3, 4, 5, 6, 7, 8, 9, 24, 43, 63, 89, ... (Sloane's A007532). These are also called handsome numbers by Rivera, and are a special case of the NARCISSISTIC NUMBERS. Powerful numbers representable in two distinct ways (*not* counting different powers of duplicated digits as distinct) are 264, 373, 375, 2132, 2223, 2241, 2243, 2245, 2263, (Sloane's A050240). Powerful numbers representable in two distinct ways (counting different powers of duplicated digits as distinct) are 224, 226, 264, 332, 334, 375, 377, 445, (Sloane's A050241).

Practical Number

A number n is practical if for all $k \leq n$, k is the sum of distinct proper divisors of n. Defined in 1948 by A. K. Srinivasen. All even PERFECT NUMBERS are practical. The number

$$m = 2^{n-1}(2^{n-1})$$

is practical for all $n = 2, 3, \ldots$. The first few practical numbers are 1, 2, 4, 6, 8, 12, 16, 18, 20, 24, 28, 30, 32, 36, 40, 42, 48, 54, 56, ... (Sloane's A005153). G. Melfi has computed twins, triplets, and 5-tuples of practical numbers. The first few 5-tuples are 12, 18, 30, 198, 306, 462, 1482, 2550, 4422, ...

Pratt Certificate

A primality certificate based on FERMAT'S LITTLE THEOREM CONVERSE. Although the general idea had been well-established for some time, Pratt became the first to prove that the certificate tree was of polynomial size and could also be verified in polynomial time. He was also the first to observe that the tree implies that PRIMES are in the complexity class NP.

To generate a Pratt certificate, assume that n is a POSITIVE INTEGER and $\{p_i\}$ is the set of PRIME FACTORS of $n-1$. Suppose there exists an INTEGER x (called a "WITNESS") such that $x^{n-1} \equiv 1 \pmod{n}$ but $x^e \not\equiv 1 \pmod{n}$ whenever e is one of $(n-1)/p_i$. Then FERMAT'S LITTLE THEOREM CONVERSE states that n is PRIME (Wagon 1991, pp. 278–79).

By applying FERMAT'S LITTLE THEOREM CONVERSE to n and recursively to each purported factor of $n-1$, a certificate for a given PRIME NUMBER can be generated. Stated another way, the Pratt certificate gives a proof that a number a is a PRIMITIVE ROOT of the multiplicative GROUP (mod p) which, along with the fact that a has order $p-1$, proves that p is a PRIME.

The figure above gives a certificate for the primality of $n = 7919$. The numbers to the right of the dashes are WITNESSES to the numbers to left. The set $\{p_i\}$ for $n-1 = 7918$ is given by $\{2, 37, 107\}$. Since $7^{7918} \equiv 1 \pmod{7919}$ but $7^{7918/2}$, $7^{7918/37}$, $7^{7918/107} \not\equiv 1 \pmod{7919}$, 7 is a WITNESS for 7919. The PRIME divisors of $7918 = 7919-$ are 2, 37, and 107. 2 is a so-called "self-WITNESS" (i.e., it is recognized as a PRIME without further ado), and the remainder of the witnesses are shown as a nested tree. Together, they certify that 7919 is indeed PRIME. Because it requires the FACTORIZATION of $n-1$, the METHOD of Pratt certificates is best applied to small numbers (or those numbers n known to have easily factorable $n-1$).

A Pratt certificate is quicker to generate for small numbers than are other types of primality certificates. The *Mathematica* task `ProvablePrimeQ[n]` in the *Mathematica* add-on package `NumberTheory`-PrimeQ`` (which can be loaded with the command `<<NumberTheory``)therefore generates an ATKIN-GOLDWASSER-KILIAN-MORAIN CERTIFICATE only for numbers above a certain limit (10^{10} by default), and a Pratt certificate for smaller numbers.

Pratt-Kasapi Theorem

HOEHN'S THEOREM

Precedes

The relationship x precedes y is written $x \prec y$. The relation x precedes or is equal to y is written $x \preccurlyeq y$.

See also SUCCEEDS

Precession

CURVE OF CONSTANT PRECESSION

Precisely Unless

If A is true precisely unless B, then B implies not-A and not-B implies A. J. H. Conway has suggested the term "UNLESSS" for this state of affairs, by analogy with IFF.

See also IFF, UNLESS

Predecessor

α is called a predecessor if there is no ORDINAL NUMBER β such that $\beta + 1 = \alpha$.

See also ORDINAL NUMBER, SUCCESSOR

Predicate

An operator in LOGIC which returns either TRUE or FALSE.

See also AND, FALSE, NAND, NOR, NOT, OR, PREDICATE CALCULUS, TRUE, XNOR, XOR

Predicate Calculus

The branch of formal LOGIC, also called functional calculus, that deals with representing the logical connections between statements as well as the statements themselves.

See also GÖDEL'S INCOMPLETENESS THEOREM, LOGIC, PREDICATE, PROPOSITIONAL CALCULUS

Predictability

Predictability at a time τ in the future is defined by

$$\frac{R(x(t),\ x(t+\tau))}{H(x(t))},$$

and linear predictability by

$$\frac{L(x(t),\ x(t+\tau))}{H(x(t))},$$

where R and L are the REDUNDANCY and LINEAR REDUNDANCY, and H is the ENTROPY.

Prediction Paradox

UNEXPECTED HANGING PARADOX

Prediction Theory

The problem of forecasting future values $X_{t+\tau}$ $(\tau > 0)$ of a weakly stationary process $\{X_t\}$ from the known values X_s $(s \leq t)$.

See also TIME SERIES ANALYSIS

References

Itô, K. (Ed.). "Prediction Theory." §395D in *Encyclopedic Dictionary of Mathematics, 2nd ed., Vol. 3.* Cambridge, MA: MIT Press, pp. 1463–465, 1987.

Predictive Value

The positive predictive value is the probability that a test gives a true result for a true statistic. The negative predictive value is the probability that a test gives a false result for a false statistic.

See also POWER (STATISTICS), SENSITIVITY, SPECIFICITY, STATISTICAL TEST

Predictor-Corrector Methods

A general set of methods for integrating ORDINARY DIFFERENTIAL EQUATIONS. Predictor-corrector methods proceed by extrapolating a polynomial fit to the derivative from the previous points to the new point (the predictor step), then using this to interpolate the derivative (the corrector step). Press *et al.* (1992) opine that predictor-corrector methods have been largely supplanted by the BULIRSCH-STOER and RUNGE-KUTTA METHODS, but predictor-corrector schemes are still in common use.

Preimage

Given $f : X \to Y$, the image of x is $f(x)$. The preimage of y is then $f^{-1}(y) = \{x | f(x) = y\}$, or all x whose image is y. Images are in the range, while preimages are in the domain (or they are empty).

Present Value

The present value v_n of a single payment made at n periods in the future is

$$v_n = \frac{p}{(1+r)^n}, \tag{1}$$

where n is the number of periods until payment, p is the payment amount, and r is the periodic discount rate. The present value v_∞ of equal payments made each successive period in perpetuity (a.k.a. the present value of a perpetuity) is given by

$$v_\infty = \sum_{n=1}^{\infty} \frac{p}{(1+r)^n} = \frac{p}{r}. \qquad (2)$$

The present value v' of equal payments made each successive period for n periods (a.k.a. the present value of an annuity) is given by

$$v' = v_\infty - v_n = \frac{p}{r}\left[1 - \frac{1}{(1+r)^n}\right], \qquad (3)$$

where p is the periodic payment amount.

Price's Theorem

Consider a GAUSSIAN BIVARIATE DISTRIBUTION in variables $\mathbf{x}$ and $\mathbf{y}$ with COVARIANCE

$$\rho = \rho_{11} = \langle \mathbf{xy} \rangle - \langle \mathbf{x} \rangle \langle \mathbf{y} \rangle$$

and an arbitrary function $g(x, y)$. Then the expected value of the random variable $g(\mathbf{x}, \mathbf{y})$

$$\langle g(\mathbf{x}, \mathbf{y}) \rangle = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} g(x, y) f(x, y)\, dx\, dy$$

satisfies

$$\frac{\partial^n \langle g(\mathbf{x}, \mathbf{y}) \rangle}{\partial \rho^n} = \left\langle \frac{\partial^{2n} g(\mathbf{x}, \mathbf{y})}{\partial \mathbf{x}^n \, \partial \mathbf{y}^n} \right\rangle.$$

Primality Certificate

A short set of data that proves the primality of a number. A certificate can, in general, be checked much more quickly than the time required to generate the certificate. Varieties of primality certificates include the PRATT CERTIFICATE and ATKIN-GOLDWASSER-KILIAN-MORAIN CERTIFICATE.

See also ATKIN-GOLDWASSER-KILIAN-MORAIN CERTIFICATE, COMPOSITENESS CERTIFICATE, PRATT CERTIFICATE

References

Wagon, S. "Prime Certificates." §8.7 in *Mathematica in Action.* New York: W. H. Freeman, pp. 277–85, 1991.

Primality Test

A test to determine whether or not a given number is PRIME. The RABIN-MILLER STRONG PSEUDOPRIME TEST is a particularly efficient ALGORITHM used by *Mathematica* version 2.2. Like many such algorithms, it is a probabilistic test using PSEUDOPRIMES, and can potentially (although with very small probability) falsely identify a COMPOSITE NUMBER as PRIME (although not vice versa). Unlike PRIME FACTORIZATION, primality testing is believed to be a P-PROBLEM (Wagon 1991). In order to guarantee primality, an almost certainly slower algorithm capable of generating a PRIMALITY CERTIFICATE must be used.

Primary

Each factor $p_i^{\alpha_i}$ in an INTEGER'S PRIME FACTORIZATION is called a primary.

Primary Pseudoperfect Number

An integer N which is a product of distinct primes and which satisfies

$$\frac{1}{N} + \sum_{p|N} \frac{1}{p} = 1$$

(Butske *et al.* 1999). The first few are 2, 6, 42, 1806, 47058, ... (Sloane's A054377).

The similar equation

$$-\frac{1}{N} + \sum_{p|N} \frac{1}{p} = 1$$

arises in the definition of GIUGA NUMBERS.

Primary Representation

Let π be a UNITARY REPRESENTATION of a GROUP G on a separable HILBERT SPACE, and let $R(\pi)$ be the smallest weakly closed algebra of bounded linear operators containing all $\pi(g)$ for $g \in G$. Then π is primary if the center of $R(\pi)$ consists of only scalar operations.

Prime

A symbol used to distinguish one quantity x' ("x'") from another related x. Primes are most commonly used to denote

1. Transformed coordinates,
2. Conjugate points,
3. DERIVATIVES,
4. The COMPLEMENT F' of a set F,
5. As an alternate notation for TRANSPOSE.

Prime Algebraic Number

An irreducible ALGEBRAIC INTEGER which has the property that, if it divides the product of two algebraic INTEGERS, then it DIVIDES at least one of the factors. 1 and -1 are the only INTEGERS which DIVIDE every INTEGER. They are therefore called the PRIME UNITS.

See also ALGEBRAIC INTEGER, PRIME UNIT

Prime Arithmetic Progression

An arithmetic progression of primes is a set of primes OF THE FORM $mk + n$ for fixed m and n and consecutive k, i.e., $\{n, m+n, 2m+n, \ldots\}$. For example, 199, 409, 619, 829, 1039, 1249, 1459, 1669, 1879, 2089 is a 10-term arithmetic progression of primes with difference 210. Let P be an increasing arithmetic progression of n PRIMES with minimal difference $d > 0$. If a PRIME $p \leq n$ does not divide d, then the elements of P must assume all residues modulo p, specifically, some element of P must be divisible by p. Since P contains only primes, this element must be equal to p.

Let the number of PRIMES OF THE FORM $mk+n$ less than x be denoted $\pi_{m,\,n}(x)$. Then

$$\lim_{x\to\infty}\frac{\pi_{a,\,b}(x)}{\mathrm{Li}(x)}=\frac{1}{\phi(a)},$$

where $\mathrm{Li}(x)$ is the LOGARITHMIC INTEGRAL and $\phi(x)$ is the TOTIENT FUNCTION.

If $d<n\#$ (where $n\#$ is the PRIMORIAL of n), then some prime $p\le n$ does not divide d, and that prime p is in P. Thus, in order to determine if P has $d<n\#$, we need only check a finite number of possible P (those with $d<n\#$ and containing prime $p\le n$) to see if they contain only primes. If not, then $d\ge n\#$. If $d=n\#$, then the elements of P cannot be made to cover all residues of any prime p. The PRIME PATTERNS CONJECTURE then asserts that there are infinitely many arithmetic progressions of primes with difference d.

A computation shows that the smallest possible common difference for a set of n or more PRIMES in arithmetic progression for $n=1, 2, 3, \ldots$ is 0, 1, 2, 6, 6, 30, 150, 210, 210, 210, 2310, 2310, 30030, 30030, 30030, 510510, ... (Sloane's A033188, Ribenboim 1989, Dubner and Nelson 1997, Wilson). The values up to $n=13$ are rigorous, while the remainder are lower bounds which assume the validity of the PRIME PATTERNS CONJECTURE and are simply given by $p_{n-7}\#$, where p_i is the ith PRIME. The smallest first terms of arithmetic progressions of n primes *with minimal differences* are 2, 2, 3, 5, 5, 7, 7, 199, 199, 199, 60858179, 147692845283, 14933623, 856378247603, ... (Sloane's A033189; Wilson).

Smaller first terms are possible for nonminimal n-term progressions. Examples include the 8-term progression $11+1210230k$ for $k=0, 1, \ldots, 7$, the 12-term progression $23143+30030k$ for $k=0, 1, \ldots, 11$ (Golubev 1969, Guy 1994), and the 13-term arithmetic progression $766439+510510k$ for $k=0, 1, \ldots, 12$ (Guy 1994).

The largest known set of primes in ARITHMETIC SEQUENCE is 22,

$$11, 410, 337, 580, 553+4, 609, 098, 694, 200k$$

for $k=0, 1, \ldots, 21$ (Pritchard *et al.* 1995, UTS School of Mathematical Sciences).

The largest known sequence of *consecutive* PRIMES in ARITHMETIC PROGRESSION (i.e., all the numbers between the first and last term in the progression, except for the members themselves, are composite) is ten, given by

$$100, 996, 972, 469, 714, 247, 637, 786, 655, 587, 969,$$
$$840, 329\,509, 324, 689, 190, 041, 803, 603, 417, 758,$$
$$904, 341, 703, 348, 882, 159, 067, 229, 719+210k$$

for $k=0, 1, \ldots, 9$ (Sloane's A033290), discovered by Harvey Dubner, Tony Forbes, Manfred Toplic, *et al.* on March 2, 1998. This beats the record of nine consecutive primes set on January 15, 1998 by the same investigators,

$$99, 679, 432, 066, 701, 086, 484, 490, 653, 695, 853,$$
$$561, 638, 982, 364, 080, 991, 618, 395, 774, 048, 585,$$
$$529, 071, 475, 461, 114, 799, 677, 694, 651+210k$$

for $k=0, 1, \ldots, 8$ (two sequences of nine are now known), the progression of eight consecutive primes given by

$$43, 804, 034, 644, 029, 893, 325, 717, 710, 709, 965,$$
$$599, 930, 101, 479, 007, 432, 825, 862, 862, 446, 333,$$
$$961, 919, 524, 977, 985, 103, 251, 510, 661+210k$$

for $k=0, 1, \ldots, 7$, discovered by Harvey Dubner, Tony Forbes, *et al.* on November 7, 1997 (several are now known), and the progression of seven given by

$$1, 089, 533, 431, 247, 059, 310, 875, 780, 378, 922, 957, 732,$$
$$908, 036, 492, 993, 138, 195, 385, 213, 105, 561, 742, 150,$$
$$447, 308, 967, 213, 141, 717, 486, 151+210k,$$

for $k=0, 1, \ldots, 6$, discovered by H. Dubner and H. K. Nelson on Aug. 29, 1995 (Peterson 1995, Dubner and Nelson 1997). The smallest sequence of six consecutive PRIMES in arithmetic progression is

$$121, 174, 811+30k$$

for $k=0, 1, \ldots, 5$ (Lander and Parkin 1967, Dubner and Nelson 1997). According to Dubner *et al.,* a trillion-fold increase in computer speed is needed before the search for a sequence of 11 consecutive primes is practical, so they expect the ten-primes record to stand for a long time to come.

It is conjectured that there are arbitrarily long sequences of PRIMES in ARITHMETIC PROGRESSION (Guy 1994). W. Roonguthai found the largest known arithmetic progression of three primes, $(3,\ 1593\cdot 2^{27757}+1,\ 1593\cdot 2^{27758}-1)$, with common difference $1593\cdot 2^{27757}-2$ (Roonguthai 1999).

Prime Array

Find the $m \times n$ ARRAY of single digits which contains the maximum possible number of PRIMES, where allowable PRIMES may lie along any horizontal, vertical, or diagonal line. For $m = n = 2$, 11 PRIMES are maximal and are contained in the two distinct arrays

$$A(2,\ 2) = \begin{bmatrix} 1 & 3 \\ 4 & 7 \end{bmatrix},\ \begin{bmatrix} 1 & 3 \\ 7 & 9 \end{bmatrix},$$

giving the PRIMES (3, 7, 13, 17, 31, 37, 41, 43, 47, 71, 73) and (3, 7, 13, 17, 19, 31, 37, 71, 73, 79, 97), respectively. For the 3×2 array, 18 PRIMES are maximal and are contained in the arrays

$$A(3,\ 2) = \begin{bmatrix} 1 & 1 & 3 \\ 9 & 7 & 4 \end{bmatrix},\ \begin{bmatrix} 1 & 7 & 2 \\ 3 & 5 & 9 \end{bmatrix},\ \begin{bmatrix} 1 & 7 & 2 \\ 4 & 3 & 9 \end{bmatrix},$$

$$\begin{bmatrix} 1 & 7 & 5 \\ 4 & 3 & 9 \end{bmatrix},\ \begin{bmatrix} 1 & 7 & 9 \\ 3 & 2 & 5 \end{bmatrix},\ \begin{bmatrix} 1 & 7 & 9 \\ 4 & 3 & 2 \end{bmatrix},$$

$$\begin{bmatrix} 1 & 7 & 9 \\ 4 & 3 & 4 \end{bmatrix},\ \begin{bmatrix} 3 & 1 & 6 \\ 4 & 7 & 9 \end{bmatrix},\ \begin{bmatrix} 3 & 7 & 6 \\ 4 & 1 & 9 \end{bmatrix}.$$

The best 3×3 array is

$$A(3,\ 3) = \begin{bmatrix} 1 & 1 & 3 \\ 7 & 5 & 4 \\ 9 & 3 & 7 \end{bmatrix},$$

which contains 30 primes: 3, 5, 7, 11, 13, 17, 31, 37, 41, 43, 47, 53, 59, 71, 73, 79, 97, 113, 157, 179, ... (Sloane's A032529). This array was found by Rivera and Ayala and shown by Weisstein in May 1999 to be maximal and unique (modulo reflection and rotation).

The best 4×4 arrays known are

$$\begin{bmatrix} 1 & 1 & 3 & 9 \\ 6 & 4 & 5 & 1 \\ 7 & 3 & 9 & 7 \\ 3 & 9 & 2 & 9 \end{bmatrix},\ \begin{bmatrix} 1 & 1 & 3 & 9 \\ 7 & 6 & 9 & 2 \\ 5 & 4 & 7 & 9 \\ 1 & 7 & 3 & 3 \end{bmatrix},$$

$$\begin{bmatrix} 1 & 7 & 3 & 3 \\ 9 & 4 & 2 & 1 \\ 6 & 5 & 9 & 1 \\ 7 & 7 & 3 & 9 \end{bmatrix},\ \begin{bmatrix} 3 & 1 & 6 & 7 \\ 7 & 5 & 1 & 4 \\ 9 & 2 & 9 & 3 \\ 3 & 3 & 7 & 3 \end{bmatrix},$$

all of which contain 63 PRIMES. The first was found by C. Rivera and J. Ayala in 1998, and the other three by James Bonfield on April 13, 1999.

The best 5×5 prime arrays known are

$$\begin{bmatrix} 1 & 1 & 9 & 3 & 3 \\ 9 & 9 & 5 & 6 & 3 \\ 8 & 9 & 4 & 1 & 7 \\ 3 & 3 & 7 & 3 & 1 \\ 3 & 2 & 9 & 3 & 9 \end{bmatrix},\ \begin{bmatrix} 3 & 3 & 1 & 9 & 9 \\ 8 & 3 & 9 & 1 & 1 \\ 2 & 7 & 4 & 5 & 7 \\ 1 & 9 & 6 & 7 & 3 \\ 9 & 7 & 9 & 1 & 9 \end{bmatrix}$$

each of which contains 116 PRIMES. The first was found by C. Rivera and J. Ayala in 1998, and the second by Wilfred Whiteside on April 17, 1999.

The best 6×6 prime arrays known are

$$\begin{bmatrix} 1 & 3 & 9 & 1 & 9 & 9 \\ 3 & 1 & 7 & 2 & 3 & 4 \\ 9 & 9 & 4 & 7 & 9 & 3 \\ 9 & 1 & 5 & 7 & 1 & 3 \\ 9 & 8 & 3 & 6 & 1 & 7 \\ 9 & 1 & 7 & 3 & 3 & 3 \end{bmatrix},\ \begin{bmatrix} 1 & 3 & 9 & 1 & 9 & 9 \\ 9 & 1 & 7 & 2 & 3 & 4 \\ 6 & 9 & 4 & 7 & 9 & 3 \\ 7 & 1 & 5 & 7 & 1 & 3 \\ 9 & 8 & 3 & 6 & 1 & 7 \\ 9 & 1 & 7 & 3 & 3 & 3 \end{bmatrix},$$

$$\begin{bmatrix} 3 & 1 & 7 & 3 & 3 & 3 \\ 9 & 9 & 5 & 6 & 3 & 9 \\ 1 & 1 & 8 & 1 & 4 & 2 \\ 1 & 3 & 6 & 3 & 7 & 3 \\ 3 & 4 & 9 & 1 & 9 & 9 \\ 3 & 7 & 9 & 3 & 7 & 9 \end{bmatrix}, \begin{bmatrix} 3 & 1 & 7 & 3 & 3 & 3 \\ 9 & 9 & 5 & 6 & 3 & 9 \\ 1 & 1 & 8 & 1 & 4 & 2 \\ 1 & 3 & 6 & 3 & 7 & 3 \\ 3 & 4 & 9 & 1 & 9 & 9 \\ 3 & 7 & 9 & 3 & 7 & 9 \end{bmatrix},$$

$$\begin{bmatrix} 3 & 1 & 7 & 3 & 3 & 3 \\ 9 & 9 & 5 & 6 & 3 & 9 \\ 1 & 1 & 8 & 1 & 4 & 2 \\ 1 & 3 & 6 & 3 & 7 & 3 \\ 3 & 4 & 9 & 1 & 9 & 9 \\ 9 & 7 & 9 & 3 & 7 & 9 \end{bmatrix}, \begin{bmatrix} 3 & 1 & 7 & 3 & 3 & 3 \\ 9 & 9 & 5 & 6 & 3 & 9 \\ 1 & 1 & 8 & 1 & 4 & 5 \\ 1 & 3 & 6 & 3 & 7 & 3 \\ 3 & 4 & 9 & 1 & 9 & 9 \\ 9 & 9 & 9 & 2 & 3 & 3 \end{bmatrix},$$

each of which contain 187 primes. One was found by S. C. Root, and the others by M. Oswald in 1998.

The best 7×7 prime array known is

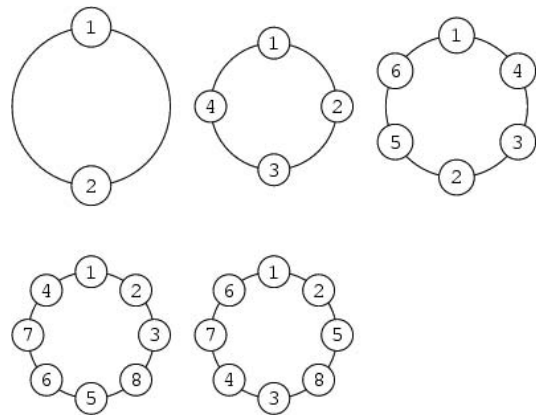
$$\begin{bmatrix} 3 & 1 & 3 & 7 & 3 & 3 & 9 \\ 9 & 9 & 2 & 3 & 3 & 3 & 3 \\ 6 & 9 & 7 & 7 & 8 & 9 & 4 \\ 7 & 6 & 1 & 5 & 9 & 1 & 9 \\ 7 & 7 & 3 & 4 & 2 & 1 & 1 \\ 9 & 9 & 4 & 7 & 9 & 3 & 9 \\ 3 & 3 & 7 & 1 & 9 & 9 & 9 \end{bmatrix},$$

which contains 281 primes and was found by Wilfred Whiteside on April 29, 1999.

The best 8×8 prime array known is

$$\begin{bmatrix} 3 & 3 & 1 & 3 & 9 & 1 & 3 & 3 \\ 6 & 9 & 3 & 3 & 7 & 3 & 9 & 7 \\ 7 & 9 & 9 & 6 & 8 & 5 & 7 & 1 \\ 9 & 7 & 9 & 9 & 1 & 2 & 4 & 9 \\ 1 & 3 & 2 & 1 & 1 & 3 & 9 & 9 \\ 6 & 3 & 9 & 1 & 9 & 4 & 6 & 3 \\ 6 & 3 & 8 & 5 & 3 & 7 & 9 & 3 \\ 9 & 1 & 3 & 1 & 3 & 9 & 3 & 3 \end{bmatrix}$$

which contains 382 primes and was found by Wilfred Whiteside On Oct. 31, 1999.



Heuristic arguments by Rivera and Ayala suggest that the maximum possible number of primes in 4×4, 5×5, and 6×6 arrays are 58–3, 112–21, and 205–18, respectively.

Prime Circle

A prime circle of order $2n$ is a free CIRCULAR PERMUTATION of the numbers from 1 to $2n$ with adjacent PAIRS summing to a PRIME. The number of prime circles for $n = 1, 2, ...,$ are 1, 1, 1, 2, 48, 512, ... (Sloane's A051252). The prime circles for the first few even orders are given in the table below.

$2n$	prime circles
2	{1, 2}
4	{1, 2, 3, 4}
6	{1, 4, 3, 2, 5, 6}
8	{1, 2, 3, 8, 5, 6, 7, 4}, {1, 2, 5, 8, 3, 4, 7, 6}

Sloane, N. J. A. Sequences A010051, A051006, and A051007 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Prime Constellation

A prime constellation, also called a prime k-tuple,- prime k-tuplet, or prime cluster, is a sequence of k consecutive numbers such that the difference between the first and last is, in some sense, the least possible. More precisely, a prime k-tuplet is a sequence of consecutive PRIMES $(p_1, p_2, ..., p_k)$ with $p_k - p_1 = s(k)$, where $s(k)$ is the smallest number s for which there exist k integers $b_1 < b_2 < \ldots < b_k$, $b_k - b_1 = s$ and, for every PRIME q, not all the residues modulo q are represented by $b_1, b_2, ..., b_k$ (Forbes). For each k, this definition excludes a finite number of clusters at the beginning of the prime number sequence. For example, (97, 101, 103, 107, 109) satisfies the conditions of the definition of a prime 5-tuplet, but (3, 5, 7, 11, 13) does not because all three residues modulo 3 are represented (Forbes).

A prime double with $s(2) = 2$ is OF THE FORM $(p, p+2)$ and is called a pair of TWIN PRIMES. Prime doubles OF THE FORM $(p, p+4)$ are called COUSIN PRIMES, and prime doubles OF THE FORM $(p, p+6)$ are called SEXY PRIMES.

A prime triplet has $s(3) = 6$. The constellation $(p, p+2, p+4)$ cannot exist, except for $p = 3$, since one of p, $p+2$, and $p+4$ must be divisible by three. However, there are several types of prime triplets which can exist: $(p, p+2, p+6)$, $(p, p+4, p+6)$, $(p, p+6, p+12)$.

A PRIME QUADRUPLET is a constellation of four successive PRIMES with minimal distance $s(4) = 8$, and is of the form $(p, p+2, p+6, p+8)$. The sequence $s(n)$ therefore begins 2, 6, 8, and continues 12, 16, 20, 26, 30, ... (Sloane's A008407). Another quadruplet constellation is $(p, p+6, p+12, p+18)$.

Hardy and Wright (1979, p. 5) conjecture, and it seems almost certain to be true, that there are infinitely many TWIN PRIMES $(p, p+2)$ and PRIME TRIPLETS OF THE FORM $(p, p+2, p+6)$ and $(p, p+4, p+6)$.

The first FIRST HARDY-LITTLEWOOD CONJECTURE states that the numbers of constellations $\leq x$ are asymptotically given by

$$P_x(p, p+2) \sim 2 \prod_{p \geq 3} \frac{p(p-2)}{(p-1)^2} \int_2^x \frac{dx'}{(\ln x')^2} = 1.320323632 \int_2^x \frac{dx'}{(\ln x')^2} \qquad (1)$$

$$P_x(p, p+4) \sim 2 \prod_{p \geq 3} \frac{p(p-2)}{(p-1)^2} \int_2^x \frac{dx'}{(\ln x')^2} = 1.320323632 \int_2^x \frac{dx'}{(\ln x')^2} \qquad (2)$$

$$P_x(p, p+6) \sim 4 \prod_{p \geq 3} \frac{p(p-2)}{(p-1)^2} \int_2^x \frac{dx'}{(\ln x')^2} = 2.640647264 \int_2^x \frac{dx'}{(\ln x')^2} \qquad (3)$$

$$P_x(p, p+2, p+6) \sim \tfrac{9}{2} \prod_{p \geq 5} \frac{p^2(p-3)}{(p-1)^3} \int_2^x \frac{dx'}{(\ln x')^3} = 2.858248596 \int_2^x \frac{dx'}{(\ln x')^3} \qquad (4)$$

$$P_x(p, p+4, p+6) \sim \tfrac{9}{2} \prod_{p \geq 5} \frac{p^2(p-3)}{(p-1)^3} \int_2^x \frac{dx'}{(\ln x')^3} = 2.858248596 \int_2^x \frac{dx'}{(\ln x')^3} \qquad (5)$$

$$P_x(p, p+2, p+6, p+8) \sim \tfrac{27}{2} \prod_{p \geq 5} \frac{p^3(p-4)}{(p-1)^4} \int_2^x \frac{dx'}{(\ln x')^4} = 4.151180864 \int_2^x \frac{dx'}{(\ln x')^4} \qquad (6)$$

$$P_x(p, p+4, p+6, p+10) \sim 27 \prod_{p \geq 5} \frac{p^3(p-4)}{(p-1)^4} \int_2^x \frac{dx'}{(\ln x')^4} = 8.302361728 \int_2^x \frac{dx'}{(\ln x')^4} \qquad (7)$$

These numbers are sometimes called the HARDY-LITTLEWOOD CONSTANTS. (1) is sometimes called the extended TWIN PRIME CONJECTURE, and

$$C_{p,\,p+2} = 2\Pi_2, \qquad (8)$$

where Π_2 is the TWIN PRIMES CONSTANT. Riesel (1994) remarks that the HARDY-LITTLEWOOD CONSTANTS can be computed to arbitrary accuracy without needing the infinite sequence of primes.

The integrals above have the analytic forms

$$\int_2^x \frac{dx'}{(\ln x')^2} = \mathrm{Li}(x) + \frac{2}{\ln 2} - \frac{n}{\ln n} \quad (9)$$

$$\int_2^x \frac{dx'}{(\ln x')^4} = \tfrac{1}{2}\mathrm{Li}(x) - \frac{x(1+\ln x)}{(\ln x)^2} + \frac{1}{\ln 2} + \frac{1}{(\ln n)^2} \quad (10)$$

$$\int_2^x \frac{dx'}{(\ln x')^3} = \frac{1}{6}\left\{\mathrm{Li}(x) + \frac{2\left[2+\ln 2+(\ln 2)^2\right]}{(\ln 2)^3}\right.$$

$$\left. - \frac{n[2+\ln n+(\ln n)^2]}{(\ln n)^3}\right\}, \quad (11)$$

where Li(x) is the LOGARITHMIC INTEGRAL.

The following table gives the number of prime constellations $\leq 10^8$, and the second table gives the values predicted by the Hardy-Littlewood formulas.

Count	10^5	10^6	10^7	10^8
$(p, p+2)$	1224	8169	58980	440312
$(p, p+4)$	1216	8144	58622	440258
$(p, p+6)$	2447	16386	117207	879908
$(p, p+2, p+6)$	259	1393	8543	55600
$(p, p+4, p+6)$	248	1444	8677	55556
$(p, p+2, p+6, p+8)$	38	166	899	4768
$(p, p+6, p+12, p+18)$	75	325	1695	9330

Hardy-Littlewood	10^5	10^6	10^7	10^8
$(p, p+2)$	1249	8248	58754	440368
$(p, p+4)$	1249	8248	58754	440368

$(p, p+2, p+6)$	279	1446	8591	55491
$(p, p+4, p+6)$	279	1446	8591	55491
$(p, p+2, p+6, p+8)$	53	184	863	4735
$(p, p+6, p+12, p+18)$				

Consider prime constellations in which each term is OF THE FORM n^2+1. Hardy and Littlewood showed that the number of prime constellations of this form $< x$ is given by

$$P(x) \sim C\sqrt{x}(\ln x)^{-1}, \quad (12)$$

where

$$C = \prod_{\substack{p>2 \\ p \text{ prime}}} \left[1 - \frac{(-1)^{(p-1)/2}}{p-1}\right] = 1.3727\ldots \quad (13)$$

(Le Lionnais 1983).

Forbes gives a list of the "top ten" prime k-tuples for $2 \leq k \leq 17$. The largest known 14-constellations are (11319107721272355839 + 0, 2, 8, 14, 18, 20, 24, 30, 32, 38, 42, 44, 48, 50), (10756418345074847279 + 0, 2, 8, 14, 18, 20, 24, 30, 32, 38, 42, 44, 48, 50), (6808488664768715759 + 0, 2, 8, 14, 18, 20, 24, 30, 32, 38, 42, 44, 48, 50), (6120794469172998449 + 0, 2, 8, 14, 18, 20, 24, 30, 32, 38, 42, 44, 48, 50), (5009128141636113611 + 0, 2, 6, 8, 12, 18, 20, 26, 30, 32, 36, 42, 48, 50).

The largest known prime 15-constellations are (84244343639633356306067 + 0, 2, 6, 12, 14, 20, 24, 26, 30, 36, 42, 44, 50, 54, 56), (89852089979514576O4337 + 0, 2, 6, 12, 14, 20, 26, 30, 32, 36, 42, 44, 50, 54, 56), (3594585413466972694697 + 0, 2, 6, 12, 14, 20, 26, 30, 32, 36, 42, 44, 50, 54, 56), (3514383375461541232577 + 0, 2, 6, 12, 14, 20, 26, 30, 32, 36, 42, 44, 50, 54, 56), (3493864509985912609487 + 0, 2, 6, 12, 14, 20, 24, 26, 30, 36, 42, 44, 50, 54, 56).

The largest known prime 16-constellations are (3259125690557440336637 + 0, 2, 6, 12, 14, 20, 26, 30, 32, 36, 42, 44, 50, 54, 56, 60), (1522014304823128379267 + 0, 2, 6, 12, 14, 20, 26, 30, 32, 36, 42, 44, 50, 54, 56, 60), (47710850533373130107 + 0, 2, 6, 12, 14, 20, 26, 30, 32, 36, 42, 44, 50, 54, 56, 60), (13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73).

The largest known prime 17-constellations are (3259125690557440336631 + 0, 6, 8, 12, 18, 20, 26, 32, 36, 38, 42, 48, 50, 56, 60, 62, 66), (17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83) (13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79).

Smith (1957) found 8 consecutive primes spaced like the cluster $\{p_n\}_{n=5}^{12}$ (Gardner 1980). K. Conrow and J. J. Devore have found 15 consecutive primes spaced like the cluster $\{p_n\}_{n=5}^{19}$ given by $\{1632373745527558118190 + p_n\}_{n=5}^{19}$, the first member of which is 1632373745527558118201.

Rivera tabulates the smallest examples of k consecutive primes ending in a given digit $d = 1$, 3, 7, or 9 for $k = 5$ to 11. For example, 216401, 216421, 216431, 216451, 216481 is the smallest set of five consecutive primes ending in the digit 1.

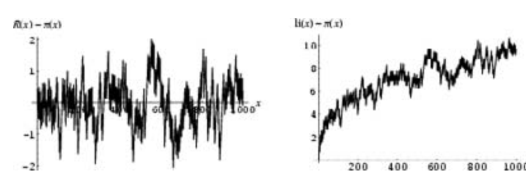
Prime Counting Function

The function $\pi(n)$ giving the number of primes $\leq n$ (Shanks 1993, p. 15). For example, there are no primes ≤ 1, so $\pi(1)=0$; there is a single prime (2) ≤ 2, so $\pi(2)=1$; there are two primes (2 and 3) ≤ 3, so $\pi(3)=2$; and so on. The first few values for n = 1, 2, ... are 0, 1, 2, 2, 3, 3, 4, 4, 4, 4, 5, 5, 6, 6, 6, ... (Sloane's A000720).



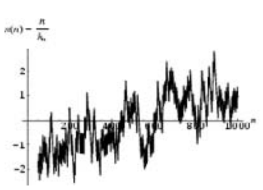
The following table gives the values of $\pi(n)$ for powers of 10 (Sloane's A006880; Hardy and Wright 1979, p. 4; Shanks 1993, pp. 242–43; Ribenboim 1996, p. 237). The value for $\pi(10^{20})$ comes from Deleglise and Rivat (1996). Note that $\pi(10^9)$ is incorrectly given as 50,847,478 in Hardy and Wright (1979) and Hardy (1999).

n	$\pi(10^n)$
3	168
4	1,229
5	9,592
6	78,498
7	664,579
8	5,761,455
9	50,847,534
10	455,052,511
11	4,118,054,813
12	37,607,912,018
13	346,065,536,839
14	3,204,941,750,802
15	29,844,570,422,669
16	279,238,341,033,925
17	2,623,557,157,654,233
18	24,739,954,287,740,860
19	234,057,667,276,344,607
20	2,220,819,602,560,918,840

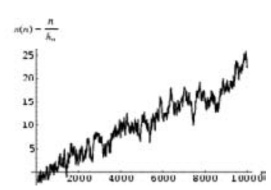
One of the most fundamental and important results in number theory is the asymptotic value of $\pi(n)$ as n becomes large. The correct formula is

$$\pi(n) \sim \mathrm{li}(n), \tag{1}$$

where $\mathrm{li}(x)$ is the logarithmic integral, which is known as the prime number theorem.



The following table compares the prime counting function $\pi(x)$, logarithmic integral $\mathrm{li}\, x$, and Riemann prime number formula $R(x)$ for small x. Note that the values given by Hardy (1999, p. 26) for $x = 10^9$ are incorrect.



x	$\pi(x)$	$\mathrm{li}\, x - \pi(x)$	$R(x) - \pi(x)$
100000	9592	38	−5
1000000	78498	130	29

2000000	148933	122	–9
3000000	216816	155	0
4000000	283146	206	33
5000000	348513	125	–64
6000000	412849	228	24
7000000	476648	179	–38
8000000	539777	223	–6
9000000	602489	187	–53
10000000	664579	339	88
100000000	5761455	754	97
1000000000	50847534	1701	–79

The prime counting function can be expressed by LEGENDRE'S FORMULA, LEHMER'S FORMULA, MAPES' METHOD, or MEISSEL'S FORMULA. A brief history of attempts to calculate $\pi(n)$ is given by Berndt (1994). The following table is taken from Riesel (1994), where $\mathcal{O}(x)$ is ASYMPTOTIC NOTATION.

Method	Time	Storage
Legendre	$\mathcal{O}(x)$	$\mathcal{O}(x^{1/2})$
Meissel	$\mathcal{O}\left(x/(\ln x)^3\right)$	$\mathcal{O}(x^{1/2}/\ln x)$
Lehmer	$\mathcal{O}\left(x/(\ln x)^4\right)$	$\mathcal{O}(x^{1/3}/\ln x)$
Mapes'	$\mathcal{O}(x^{0.7})$	$\mathcal{O}(x^{0.7})$
Lagarias-Miller-Odlyzko	$\mathcal{O}\left(x^{2/3+\epsilon}\right)$	$\mathcal{O}\left(x^{1/3+\epsilon}\right)$
Lagarias-Odlyzko 1	$\mathcal{O}\left(x^{3/5+\epsilon}\right)$	$\mathcal{O}(x^{\epsilon})$
Lagarias-Odlyzko 2	$\mathcal{O}\left(x^{1/2+\epsilon}\right)$	$\mathcal{O}\left(x^{1/4+\epsilon}\right)$

An approximate formula due to Locker-Ernst (Locker-Ernst 1959, Panaitopol 1999), illustrated above, is given by

$$\pi(n) \approx \frac{n}{h_n}, \tag{2}$$

where h_n is related to the HARMONIC NUMBER H_n by $h_n = H_n - 3/2$. This formula is within ≈ 2 of the actual value for $50 \leq n \leq 1000$. The values for which $\pi - n/h_n > 0$ are 1, 109, 113, 114, 199, 200, 201, ... (Sloane's A051046). Panaitopol (1999) shows that this quantity is positive for all $n \geq 1429$.

An upper limit for $\pi(n)$ is given by

$$\pi(n) < \frac{2n-6}{\ln n} \tag{3}$$

(Rosser and Schoenfeld 1962). Hardy and Wright (1979, p. 414) give the formula

$$\pi(n) = -1 + \sum_{j=3}^{n} \left[(j-2)! - j \left\lfloor \frac{(j-2)!}{j} \right\rfloor \right], \tag{4}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

A modified version of the prime counting function is given by

$$\pi_0(p) \equiv \begin{cases} \pi(p) & \text{for } p \text{ composite} \\ \pi(p) - \frac{1}{2} & \text{for } p \text{ prime} \end{cases}$$

$$\pi_0(p) = \sum_{n=1}^{\infty} \frac{\mu(x) f\left(x^{1/n}\right)}{n},$$

where $\mu(n)$ is the MÖBIUS FUNCTION and $f(x)$ is the RIEMANN FUNCTION.

The notation $\pi_{a,\,b}$ is also used to denote the number of PRIMES OF THE FORM $ak+b$ (Shanks 1993, pp. 21–2). Groups of EQUINUMEROUS values of $\pi_{a,\,b}$ include ($\pi_{3,\,1}$, $\pi_{3,\,2}$), ($\pi_{4,\,1}$, $\pi_{4,\,3}$), ($\pi_{5,\,1}$, $\pi_{5,\,2}$, $\pi_{5,\,3}$, $\pi_{5,\,4}$), ($\pi_{6,\,1}$, $\pi_{6,\,5}$), ($\pi_{7,\,1}$, $\pi_{7,\,2}$, $\pi_{7,\,3}$, $\pi_{7,\,4}$, $\pi_{7,\,5}$, $\pi_{7,\,6}$), ($\pi_{8,\,1}$, $\pi_{8,\,3}$, $\pi_{8,\,5}$, $\pi_{8,\,7}$), ($\pi_{9,\,1}$, $\pi_{9,\,2}$, $\pi_{9,\,4}$, $\pi_{9,\,5}$, $\pi_{9,\,7}$, $\pi_{9,\,8}$), and so on. The values of $\pi_{n,k}$ for small n are given in the following table for the first few powers of ten (Shanks 1993).

n	$\pi_{3,\,1}(n)$	$\pi_{3,\,2}(n)$	$\pi_{4,\,1}(n)$	$\pi_{4,\,3}(n)$
10^1	1	2	1	2
10^2	11	13	11	13
10^3	80	87	80	87
10^4	611	617	609	619
10^5	4784	4807	4783	4808
10^6	39231	39266	39175	39322
10^7	332194	332384	332180	332398

n	$\pi_{5,\,1}(n)$	$\pi_{5,\,2}(n)$	$\pi_{5,\,3}(n)$	$\pi_{5,\,4}(n)$
10^1	0	2	1	0
10^2	5	7	7	5
10^3	40	47	42	38
10^4	306	309	310	303

10^5	2387	2412	2402	2390
10^6	19617	19622	19665	19593
10^7	166104	166212	166230	166032

n	$\pi_{6,1}(n)$	$\pi_{6,5}(n)$
10^1	1	1
10^2	11	12
10^3	80	86
10^4	611	616
10^5	4784	4806
10^6	39231	39265

n	$\pi_{7,1}$	$\pi_{7,2}$	$\pi_{7,3}$	$\pi_{7,4}$	$\pi_{7,5}$	$\pi_{7,6}$
10^1	0	1	1	0	1	0
10^2	3	4	5	3	5	4
10^3	28	27	30	26	29	27
10^4	203	203	209	202	211	200
10^5	1593	1584	1613	1601	1604	1596
10^6	13063	13065	13105	13069	13105	13090

n	$\pi_{8,1}(n)$	$\pi_{8,3}(n)$	$\pi_{8,5}(n)$	$\pi_{8,7}(n)$
10^1	0	1	1	1
10^2	5	7	6	6
10^3	37	44	43	43
10^4	295	311	314	308
10^5	2384	2409	2399	2399
10^6	19552	19653	19623	19669
10^7	165976	166161	166204	166237

Note that since $\pi_{8,1}(n)$, $\pi_{8,3}(n)$, $\pi_{8,5}(n)$, and $\pi_{8,7}(n)$ are EQUINUMEROUS,

$$\pi_{4,1}(n) = \pi_{8,1}(n) + \pi_{8,5}$$

$$\pi_{4,3}(n) = \pi_{8,3}(n) + \pi_{8,7}$$

are also equinumerous.

Erdos proved that there exist at least one PRIME OF THE FORM $4k+1$ and at least one PRIME of the form $4k+3$ between n and $2n$ for all $n > 6$.

The smallest x such that $x \geq n\pi(x)$ for $n = 2, 3, \ldots$ are 2, 27, 96, 330, 1008, ... (Sloane's A038625), and the corresponding $\pi(x)$ are 1, 9, 24, 66, 168, 437, ... (Sloane's A038626). The number of solutions of $x \geq n\pi(x)$ for $n = 2, 3, \ldots$ are 4, 3, 3, 6, 7, 6, ... (Sloane's A038627).

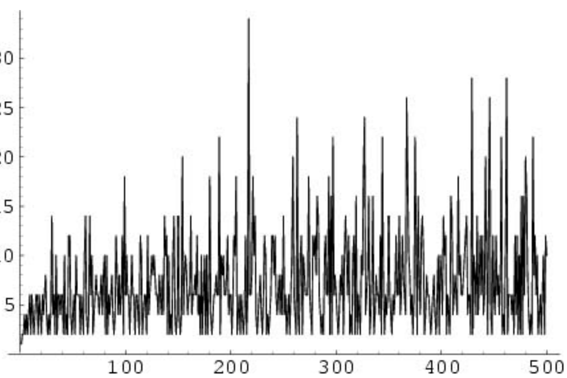
Prime Cut



Find two numbers such that $x^2 \equiv y^2 \pmod{n}$. If you know the GREATEST COMMON DIVISOR of n and $x-y$, there exists a high probability of determining a PRIME factor. Taking small numbers x which additionally give small PRIMES $x^2 \equiv p \pmod{n}$ further increases the chances of finding a PRIME FACTOR.

See also GREATEST COMMON DIVISOR

Prime Decomposition

PRIME FACTORIZATION

Prime Difference Function

$$d_n \equiv p_{n+1} - p_n.$$

The first few values are 1, 2, 2, 4, 2, 4, 2, 4, 6, 2, 6, 4, 2, 4, 6, 6, ... (Sloane's A001223). Rankin has shown that

$$d_n > \frac{c \ln n \ln \ln n \ln \ln \ln \ln n}{(\ln \ln \ln n)^2}$$

for infinitely many n and for some constant c (Guy 1994).

An integer n is called a JUMPING CHAMPION if n is the most frequently occurring difference between consecutive primes $n \le N$ for some N (Odlyzko *et al.*).

Prime Divisor

If $f(x)$ is a nonconstant INTEGER POLYNOMIAL and c is an integer such that $f(c)$ is divisible by the prime p, that p is called a prime divisor of the polynomial $f(x)$

(Nagell 1951, p. 81). Every INTEGER POLYNOMIAL $f(x)$ which is not a constant has an infinite number of prime divisors (Nagell 1951, p. 82).

References

Nagell, T. "Prime Divisors of Integral Polynomials." §25 in *Introduction to Number Theory.* New York: Wiley, pp. 81–3, 1951.

Prime Factorization

The FACTORIZATION of a numbers into its constituent PRIMES, also called prime decomposition. Given a POSITIVE INTEGER $n \geq 2$, the prime factorization is written

$$n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_k^{\alpha_k},$$

where the p_is are the k PRIME FACTORS, each of order α_i. Each factor $p_i^{\alpha_i}$ is called a PRIMARY. The first few prime factorizations (the number 1, by definition, has a prime factorization of "1") are given in the following table.

1	1	11	11
2	2	12	$2^2 \cdot 3$
3	3	13	13
4	2^2	14	$2 \cdot 7$
5	5	15	$3 \cdot 5$
6	$2 \cdot 3$	16	2^4
7	7	17	17
8	2^3	18	$2 \cdot 9$
9	3^2	19	19
10	$2 \cdot 5$	20	$2^2 \cdot 5$

The number of *digits* in the prime factorization of $n = 1, 2, ...,$ are 1, 1, 1, 2, 1, 2, 1, 2, 2, 2, 2, 3, (Sloane's A050252).

In general, prime factorization is a difficult problem, and many sophisticated PRIME FACTORIZATION ALGORITHMS have been devised for special types of numbers.

Prime Factorization Algorithms

Many ALGORITHMS have been devised for determining the PRIME FACTORS of a given number (a process called PRIME FACTORIZATION). They vary quite a bit in sophistication and complexity. It is very difficult to build a general-purpose algorithm for this computationally "hard" problem, so any additional information which is known about the number in question or its factors can often be used to save a large amount of time.

The simplest method of finding factors is so-called "DIRECT SEARCH FACTORIZATION" (a.k.a. TRIAL DIVISION). In this method, all possible factors are systematically tested using trial division to see if they actually DIVIDE the given number. It is practical only for very small numbers.

The fastest-known fully proven deterministic algorithm is the Pollard-Strassen method (Pomerance 1987; Hardy *et al.* 1990).

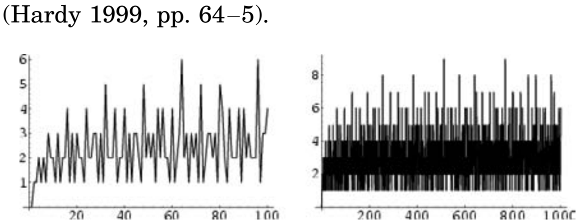
Prime Factors

The number of DISTINCT PRIME FACTORS of a number n is denoted $\omega(n)$. $\omega(n)$ therefore corresponds to a prime factorization OF THE FORM

$$n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_{\omega(n)}^{\alpha_{\omega(n)}}. \tag{1}$$

The first few values for $n = 1, 2, \ldots$ are 0, 1, 1, 1, 1, 2, 1, 1, 1, 2, 1, 2, 1, 2, 2, 1, 1, 2, 1, 2, ... (Sloane's A001221).



The first few numbers u_n which are products of an odd number of distinct prime factors (Hardy 1999, p. 64; Ramanujan 2000, pp. xxiv and 21) are 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 30, 31, 37, 41, 42 43, 47, ... (Sloane's A030059). u_n satisfies

$$\sum_{n=1}^{\infty} \frac{1}{u_n^s} = \frac{1}{2}\left[\frac{\zeta(s)}{\zeta(2s)} - \zeta(s)\right] \tag{2}$$

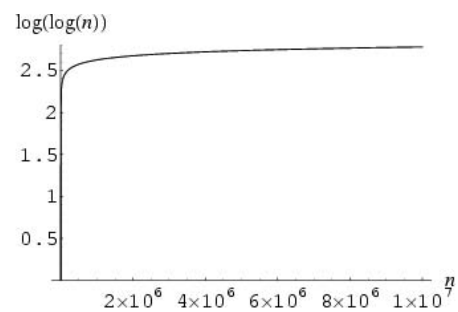
(Hardy 1999, pp. 64–5). In addition, if $U(n)$ is the number of u_k with $k \le n$, then

$$U(x) \sim \frac{3x}{\pi^2} \tag{3}$$

(Hardy 1999, pp. 64–5).

The number of *not necessarily distinct* prime factors of a number n is denoted $r(n)$. The first few values for $n = 1, 2, \ldots$ are 0, 1, 1, 2, 1, 2, 1, 3, 2, 2, 1, 3, 1, 2, 2, 4, 1, 3, 1, 3, ... (Sloane's A001222). If n is chosen at random between 1 and x, then the probability that $r(n) \le \ln n \ln n + c\sqrt{\ln \ln x}$ approaches

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{c} e^{-u^2/2}\, du \tag{4}$$



(Knuth 1998, p. 384). In addition, the average value $\bar{t}$ of $r(n) - \ln \ln x$ for $1 \le n \le x$ approaches

$$\bar{t} = \gamma + \sum_{p \text{ prime}} \left[\ln\left(1 - \frac{1}{p}\right) + \frac{1}{p-1}\right] \tag{5}$$

$$= \gamma + \sum_{n=2}^{\infty} \frac{\phi(n) \ln[\zeta(n)]}{n} \tag{6}$$

$$\approx 1.0345638819, \tag{7}$$

where γ is the EULER-MASCHERONI CONSTANT, $\phi(n)$ is the TOTIENT FUNCTION, and $\zeta(n)$ is the RIEMANN ZETA FUNCTION.

The average orders of both $\omega(n)$ and $r(n)$ are

$$\omega(n) \sim \ln \ln n \tag{8}$$

(Hardy 1999, p. 51). More precisely,

$$\sum_{n \le x} \omega(n) = x \ln \ln x + Ax + \mathcal{O}\left(\frac{x}{\ln x}\right) \tag{9}$$

$$\sum_{n \le x} r(n) = x \ln \ln x + Bx + \mathcal{O}\left(\frac{x}{\ln x}\right) \tag{10}$$

for appropriate constants A and B (Hardy and Ramanujan 1917; Hardy and Wright 1979, p. 355; Hardy 1999, p. 57), where $\mathcal{O}(x)$ is ASYMPTOTIC NOTATION.

The following table gives the prime factors for the positive integers ≤ 50.

1	1	11	11	21	$3 \cdot 7$	31	31	41	41
2	2	12	$2^2 \cdot 3$	22	$2 \cdot 11$	32	2^5	42	$2 \cdot 3 \cdot 7$
3	3	13	13	23	23	33	$3 \cdot 11$	43	43
4	2^2	14	$2 \cdot 7$	24	$2^3 \cdot 3$	34	$2 \cdot 17$	44	$2^2 \cdot 11$

5	5	15	$3 \cdot 5$	25	5^2	35	$5 \cdot 7$	45	$3^3 \cdot 5$
6	$2 \cdot 3$	16	2^4	26	$2 \cdot 13$	36	$2^2 \cdot 3^2$	46	$2 \cdot 23$
7	7	17	17	27	3^3	37	37	47	47
8	2^3	18	$2 \cdot 3^2$	28	$2^2 \cdot 7$	38	$2 \cdot 19$	48	$2^4 \cdot 3$
9	3^2	19	19	29	29	39	$3 \cdot 13$	49	7^2
10	$2 \cdot 5$	20	$2^2 \cdot 5$	30	$2 \cdot 3 \cdot 5$	40	$2^3 \cdot 5$	50	$2 \cdot 5^2$

Prime Field

A FINITE FIELD $GF(p)$ where p is PRIME.

Prime Formulas

There exist a variety of formulas for producing either the nth prime as a function of n, or else taking on only prime values. However, all such formula require either extremely accurate knowledge of some unknown constant, or else effectively require knowledge of the primes ahead of time in order to use the formula (Dudley 1969, Ribenboim 1996, p. 186).

For example, there exists a CONSTANT $\theta = 1.3063\ldots$ (Sloane's A051021) known as MILLS' CONSTANT such that

$$f(n) = \lfloor \theta^{3^n} \rfloor, \tag{1}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, is prime for all $n \geq 1$ (Ribenboim 1996, p. 186). The first few values of $f(n)$ are 2, 11, 1361, 2521008887, ... (Sloane's A051254). It is not known if θ is IRRATIONAL. There also exists a CONSTANT $\omega \approx 1.9287800$ such that

$$g(n) = \left\lfloor \underbrace{2^{2^{\cdot^{\cdot^{2^{\omega}}}}}}_{n} \right\rfloor \tag{2}$$

(Wright 1951; Ribenboim 1996, p. 186) is prime for every $n \geq 1$. The first few values of $g(n)$ are 3, 13, 16381, ... In the case of both $f(n)$ and $g(n)$, the numbers at $n = 4$ grow so rapidly that an extremely precise value of θ or ω is needed in order to obtain the correct value. Values for $n \geq 5$ are hopeless.

Explicit FORMULAS exist for the nth prime both as a function of n and in terms of the primes 2, ..., p_{n-1} (Hardy and Wright 1979, pp. 5–, 344–45, and 414; Guy 1994, pp. 36–1). Let

$$F(j) = \left\lfloor \cos^2 \left[\pi \frac{(j-1)! + 1}{j} \right] \right\rfloor \tag{3}$$

for integral $j > 1$, where $\lfloor x \rfloor$ is again the FLOOR FUNCTION. Then

$$p_n = 1 + \sum_{m=1}^{2^n} \left\lfloor \left\lfloor \frac{n}{\sum_{j=1}^{m} F(j)} \right\rfloor^{1/n} \right\rfloor \tag{4}$$

$$= 1 + \sum_{m=1}^{2^n} \left\lfloor \left\lfloor \frac{n}{1 + \pi(m)} \right\rfloor^{1/n} \right\rfloor, \tag{5}$$

where $\pi(m)$ is the PRIME COUNTING FUNCTION. This formula conceals the prime numbers j as those for which $F(j) = 1$, i.e., the values of $F(j)$ are 1, 1, 1, 0, 1, 0, 1, 0, 0, 0, 1, ...

Gandhi gave the formula in which p_{n+1} is the unique integer such that

$$1 < 2^{p_{n+1}} \left(\sum_{d \mid p_n\#} \frac{\mu(d)}{2^d - 1} - \frac{1}{2} \right) < 2, \tag{6}$$

where $p_n\#$ is the PRIMORIAL function (Gandhi 1971, Eynden 1972, Golomb 1974) and $\mu(n)$ is the MÖBIUS FUNCTION. It is also true that

$$p_{n+1} = 1 + p_n + F(p_n + 1) + F(p_n + 1) + F(p_n + 2)$$
$$+ \prod_{j=1}^{p} F(p_n + j) \tag{7}$$

(Ribenboim 1996, pp. 180–82). Note that the number of terms in the summation to obtain the nth prime is 2^n, so these formulas turn out not to be practical in the study of primes. An interesting INFINITE PRODUCT formula due to Euler which relates π and the nth PRIME p_n is

$$\pi = \frac{2}{\prod_{i=n}^{\infty}\left[1+\frac{\sin\left(\frac{1}{2}\pi p_n\right)}{p_n}\right]} \tag{8}$$

$$= \frac{2}{\prod_{i=n}^{\infty}\left[1+\frac{(-1)^{(p_n-1)/2}}{p_n}\right]} \tag{9}$$

(Blatner 1997). Hardy and Wright (1979, p. 414) give the formula

$$p_n = 1 + \sum_{j=1}^{2^n} f(n,\ \pi(j)), \tag{10}$$

for $n > 3$, where

$$f(x,\ y) = \begin{cases} 0 & \text{for } x = y \\ \frac{1}{2}\left[1+\frac{x-y}{|x-y|}\right] & \text{for } x \neq y \end{cases} \tag{11}$$

and

$$\pi(n) = -1 + \sum_{j=3}^{n}\left[(j-2)! - j\left\lfloor\frac{(j-2)!}{j}\right\rfloor\right] \tag{12}$$

(correcting a sign error), where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

A double sum for the nth prime p_n is

$$p_n = 1 + \sum_{k=1}^{2(\lfloor n \ln n \rfloor + 1)}\left[1 - \left\lfloor\frac{\sum_{j=2}^{k} 1 + \lfloor s(j) \rfloor}{n}\right\rfloor\right], \tag{13}$$

where

$$s(j) \equiv -\frac{\sum_{s=1}^{j}\left(\left\lfloor\frac{j}{s}\right\rfloor - \left\lfloor\frac{j-1}{s}\right\rfloor\right) - 2}{j} \tag{14}$$

(Ruiz 2000).

B. M. Bredihin proved that

$$f(x,\ y) = x^2 + y^2 + 1 \tag{15}$$

takes prime values for infinitely many integral pairs $(x,\ y)$ (Honsberger 1976, p. 30). In addition, the function

$$f(x,y) = \tfrac{1}{2}(y-1)\left\lfloor\left|B^2(x,\ y)-1\right| - \left(B^2(x,\ y)-1\right)\right\rfloor + 2, \tag{16}$$

where

$$B(x,\ y) = x(y+1) - (y!+1), \tag{17}$$

$y!$ is the FACTORIAL, and $\lfloor x \rfloor$ is the FLOOR FUNCTION, generates only prime numbers for POSITIVE INTEGER arguments. It not only generates every prime number, but generates ODD PRIMES exactly once each, with all other values being 2 (Honsberger 1976, p. 33). For example,

$$f(1,\ 2) = 3 \tag{18}$$

$$f(5,\ 4) = 5 \tag{19}$$

$$f(103,\ 6) = 7, \tag{20}$$

with no new primes generated for $x,\ y \leq 1000$.

Conway (Guy 1983, Conway and Guy 1996, p. 147) gives an algorithm for generating primes based on 14 fractions, but it is actually just a concealed version of a SIEVE.

Prime Gaps

Letting

$$d_n \equiv p_{n+1} - p_n \tag{1}$$

be the PRIME DIFFERENCE FUNCTION, Rankin has showed that

$$d_n > \frac{c \ln n \ln \ln n \ln \ln \ln \ln n}{(\ln \ln \ln n)^2} \qquad (2)$$

for infinitely many n and for some constant c (Guy 1994).

Let $p(d)$ be the smallest PRIME following d or more consecutive COMPOSITE NUMBERS. The largest known is

$$p(804) = 90,874,329,412,297. \qquad (3)$$

The largest known prime gap is of length 4247, occurring following $10^{314} - 1929$ (Baugh and O'Hara 1992), although this gap is almost certainly not maximal (i.e., there probably exists a smaller number having a gap of the same length following it). Cramér (1937) and Shanks (1964) conjectured that a maximal gap $p(n)$ of length n first appears at approximately

$$p(n) \sim \exp(\sqrt{n}). \qquad (4)$$

Wolf conjectures a slightly different form

$$p(n) \sim \sqrt{n} \exp(\sqrt{n}), \qquad (5)$$

which agrees better with numerical evidence.

Wolf conjectures that the maximal gap $G(n)$ between two consecutive primes less than n appears approximately at

$$G(n) \sim \frac{n}{\pi(n)}[2 \ln \pi(n) - \ln n + \ln(2C_2)] \equiv g(n), \qquad (6)$$

where $\pi(n)$ is the PRIME COUNTING FUNCTION and C_2 is the TWIN PRIMES CONSTANT. Setting $\pi(n) \sim n/\ln n$ reduces to Cramer's conjecture for large n,

$$G(n) \sim (\ln n)^2. \qquad (7)$$

Let $c(n)$ be the smallest starting INTEGER $c(n)$ for a run of n consecutive COMPOSITE NUMBERS, also called a COMPOSITE RUN. No general method other than exhaustive searching is known for determining the first occurrence for a maximal gap, although arbitrarily large gaps exist (Nicely 1998). The first few $c(n)$ for $n = 1, 2, \ldots$ are 4, 8, 8, 24, 24, 90, 90, 114, ... (Sloane's A030296).

The following table gives the sequence of maximal prime gaps, omitting degenerate runs which are part of a run with greater n. It is a complete list of smallest maximal runs up to 10^{16} (Nicely, pers. comm., May 30, 2000). $c(n)$ in this table is given by Sloane's A008950, and n by Sloane's A008996. The ending integers for the run corresponding to $c(n)$ are given by Sloane's A008995. Young and Potler (1989) determined the first occurrences of prime gaps up to 72,635,119,999,997, with all first occurrences found between 1 and 673. Nicely (1998) extended the list of maximal prime gaps to a length of 915, denoting gap lengths by the difference of bounding PRIMES, $c(n) - 1$.

n	$c(n)$	n	$c(n)$

Prime Group

When the ORDER h of a finite GROUP is a PRIME NUMBER, there is only one possible GROUP of ORDER h. Furthermore, the GROUP is CYCLIC.

See also P-GROUP

Prime Ideal

An IDEAL I such that if $ab \in I$, then either $a \in I$ or $b \in I$. For example, in the integers, the IDEAL $\mathfrak{a} = \langle p \rangle$ (i.e., the multiples of p) is prime whenever p is a PRIME NUMBER.

Prime ideals are useful when the ring in question is not necessarily a PRINCIPAL IDEAL DOMAIN, e.g., $\mathfrak{a} = \langle 2, \sqrt{6} \rangle$ in $\mathbb{Z}[\sqrt{6}]$. The general element of $\mathfrak{a}$ can be written as $2a + b\sqrt{6}$ where a and b can be any integers. Suppose that

$$\left(x_1 + x_2\sqrt{6}\right)\left(y_1 + y_2\sqrt{6}\right) = 2a + b\sqrt{6},$$

then $x_1 y_1 + 6x_2 y_2 = 2a$. So either x_1 or y_1 has to be even. The corresponding factor $\left(x_1 + x_2\sqrt{6}\right)$ or $\left(y_1 + y_2\sqrt{6}\right)$ has to be in $\mathfrak{a} = \langle 2, \sqrt{6} \rangle$. Hence, the ideal $\mathfrak{a}$ is prime. Note that this ring does not have UNIQUE FACTORIZATION since $2 \cdot 3 = 6 = \sqrt{6} \cdot \sqrt{6}$.

One consequence of the definition is that the set of elements not in a prime ideal, $R - \mathfrak{p}$, is CLOSED under multiplication. This allows one to LOCALIZE at $\mathfrak{p}$ by considering the RING OF FRACTIONS. This ring is analogous to the construction of the rationals as fractions of integers, except that the denominator must be in $R - \mathfrak{p}$. The only MAXIMAL IDEAL in this ring is the EXTENSION of $\mathfrak{p}$.

From the perspective of ALGEBRAIC GEOMETRY, ideals correspond to VARIETIES. Because multiplication corresponds to union (such as $xy = 0$ implies $x = 0$ or $y = 0$), a prime ideal corresponds to an IRREDUCIBLE VARIETY.

Prime Knot

A KNOT other than the UNKNOT which cannot be expressed as a sum of two other KNOTS, neither of which is unknotted. A KNOT which is not prime is called a COMPOSITE KNOT. It is often possible to combine two prime knots to create two different COMPOSITE KNOTS, depending on the orientation of the two. Schubert (1949) showed that every knot can be uniquely decomposed (up to the order in which the decomposition is performed) as a KNOT SUM of prime knots.

There is no known FORMULA for giving the number of distinct prime knots as a function of the number of crossings. The numbers of distinct prime knots having $n = 1, 2, \ldots$ crossings are 0, 0, 1, 2, 3, 7, 21, 49, 165, 552, 2176, 9988, ... (Sloane's A002863). Hoste *et al.* (1998) computed the number of distinct prime knots of n crossing up to $n = 16$. Let $N(n)$ be the number of distinct PRIME KNOTS of n crossings, *counting CHIRAL versions of the same knot separately.* Then

$$\tfrac{1}{3}\left(2^{n-2} - 1\right) \leq N(n) \lesssim e^n$$

(Ernst and Summers 1987). Welsh has shown that the number of knots is bounded by an exponential in n, and it is also known that

$$\lim\ \sup[N(n)]^{1/n} < 13.5$$

(Welsh 1991, Hoste *et al.* 1998, Thistlethwaite 1998).

Menasco (1984) showed that a reduced alternating diagram represents a prime knot IFF the diagram is itself prime ("an alternating knot is prime IFF it looks prime"; Hoste *et al.* 1998).

Prime Number

A prime number (or prime integer, often simply called a "prime" for short) is a POSITIVE INTEGER $p>1$ that has no positive integer DIVISORS other than 1 and p itself. (More concisely, a prime number p is a POSITIVE INTEGER having exactly one positive divisor other than 1.) For example, the only divisors of 13 are 1 and 13, making 13 a prime number, while the number 24 has divisors 1, 2, 3, 4, 6, 8, 12, and 24 (corresponding to the factorization $24=2^3 \cdot 3$), making 24 *not* a prime number. POSITIVE INTEGERS other than 1 which are not prime are called COMPOSITE NUMBERS. The number 1 is a special case which is considered neither prime nor composite (Wells 1986, p. 31).

Although the number 1 used to be considered a prime (Lehmer 1909; Lehmer 1914; Hardy and Wright 1979, p. 11; Sloane and Plouffe 1995, p. 33; Hardy 1999, p. 46), it requires special treatment in so many definitions and applications involving primes greater than or equal to 2 that it is usually placed into a class of its own. As noted by Tietze (1965, p. 2), "Why is the number 1 made an exception? This is a problem that schoolboys often argue about, but since it is a question of definition, it is not arguable." The smallest prime is therefore 2. However, since 2 is the only EVEN PRIME, it is also somewhat special, the set of all primes excluding 2 is called the "ODD PRIMES." Note also that while 2 is considered a prime today, at one time it was not (Tietze 1965, p. 18; Tropfke 1921, p. 96). *Excluding* 1 and *including* 2, the first few primes are 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, ... (Sloane's A000040; Hardy and Wright 1979, p. 3), and the SET of primes is sometimes denoted $\mathbb{P}$.

While the term "prime number" commonly refers to prime positive integers, other types of primes are also defined, such as the GAUSSIAN PRIMES.

The function which gives the number of primes less than a number n is denoted $\pi(n)$ and is called the PRIME COUNTING FUNCTION. The theorem giving an asymptotic form for $\pi(n)$ is called the PRIME NUMBER THEOREM. Prime numbers can be generated by sieving processes (such as the ERATOSTHENES SIEVE), and LUCKY NUMBERS, which are also generated by sieving, appear to share some interesting asymptotic properties with the primes. Prime numbers satisfy many strange and wonderful properties. Although there exist explicit PRIME FORMULAS (i.e., formulas which either generate primes for all values or else the nth prime as a function of n), they are contrived to such an extent that they are of little practical value.

Many PRIME FACTORIZATION ALGORITHMS have been devised for determining the prime factors of a given INTEGER, a process known as factorization or prime factorization. They vary quite a bit in sophistication and complexity. It is *very* difficult to build a general-purpose algorithm for this computationally "hard" problem, so any additional information which is known about the number in question or its factors can often be used to save a large amount of time. It should be emphasized that although no efficient algorithms are known for factoring arbitrary primes, it has not been *proved* that no such algorithm exists. It is therefore conceivable that a suitably clever person could devise a general method of factoring which would render the vast majority of encryption schemes in current widespread use, including those used by banks and governments, easily breakable.

Because of their importance in encryption algorithms such as RSA ENCRYPTION, prime numbers can be important commercial commodities. In fact, Roger Schlafly has obtained U.S. Patent 5,373,560 (12/13/94) on the following two primes (expressed in hexadecimal notation):

```
98A3DF52AEAE9799325CB258D767EBD1F4630E9B

95A5B90B276E44F9.

The FUNDAMENTAL THEOREM OF ARITHMETIC states that any POSITIVE INTEGER can be represented in exactly one way as a PRODUCT of primes. EUCLID'S SECOND THEOREM demonstrated that there are an infinite number of primes. However, it is not known if there are an infinite number of primes OF THE FORM n^2+1 (Hardy and Wright 1979, p. 19; Ribenboim 1996, pp. 206–08), whether there are an INFINITE number of TWIN PRIMES (the TWIN PRIME CONJECTURE), or if a prime can always be found between n^2 and $(n+1)^2$ (Hardy and Wright 1979, p. 415; Ribenboim 1996, pp. 397–98). The latter two of these are two of LANDAU'S PROBLEMS.

The simplest method of finding factors is so-called "DIRECT SEARCH FACTORIZATION" (a.k.a. TRIAL DIVISION). In this method, all possible factors are systematically tested using trial division to see if they actually DIVIDE the given number. It is practical only for very small numbers. More general (and complicated) methods include the ELLIPTIC CURVE FACTORIZATION METHOD and NUMBER FIELD SIEVE factorization method.

It has been proven that the set of prime numbers is a DIOPHANTINE SET (Ribenboim 1991, pp. 106–07). Ramanujan also showed that

$$\frac{d\pi(x)}{dx} \sim \frac{1}{x \ln x} \sum_{n=1}^{\infty} \frac{\mu(n)}{n} x^{1/n}, \tag{1}$$

where $\pi(x)$ is the PRIME COUNTING FUNCTION and $\mu(n)$ is the MÖBIUS FUNCTION (Berndt 1994, p. 117).

With the exception of 2 and 3, all primes are of the form $p = 6n \pm 1$, i.e., $p \equiv 6 \pmod{1, 5}$. For n an INTEGER ≥ 2, n is prime IFF

$$\binom{n-1}{k} \equiv (-1)^k \pmod{n} \tag{2}$$

for $k = 0, 1, \ldots, n-1$ (Deutsch 1996), where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. In addition, an integer n is prime IFF

$$\phi(n) + \sigma(n) = 2n. \tag{3}$$

The first few composite n for which $n \mid [\phi(n) + \sigma(n)]$ are $n = 312, 560, 588, 1400, 23760, \ldots$ (Sloane's A011774; Guy 1997), with a total of 18 such numbers less than 2×10^7.

Cheng (1979) showed that for x sufficiently large, there always exist at least two prime factors between $(x - x^{\alpha})$ and x for $\alpha \geq 0.477\ldots$ (Le Lionnais 1983, p. 26). Let $f(n)$ be the number of decompositions of n into two or more consecutive primes. Then

$$\lim_{x\to\infty} \frac{1}{x} \sum_{n=1}^{x} f(n) = \ln 2 \tag{4}$$

(Moser 1963, Le Lionnais 1983, p. 30).

The probability that the GREATEST PRIME FACTOR of a RANDOM integer n is greater than $\sqrt{n}$ is $\ln 2$ (Schroeppel 1972). The probability that two INTEGERS picked at random are RELATIVELY PRIME is $[\zeta(2)]^{-1} = 6/\pi^2$, where $\zeta(x)$ is the RIEMANN ZETA FUNCTION (Cesaro and Sylvester 1883). Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)^{-1}] \approx 1.20206^{-1} \approx 0.831907, \tag{5}$$

where $\zeta(3)$ is APÉRY'S CONSTANT. In general, the probability that n random numbers lack a pth POWER common divisor is $[\zeta(np)]^{-1}$ (Beeler *et al.* 1972, Item 53).

Large primes include the large MERSENNE PRIMES, FERRIER'S PRIME, and $391581 \cdot 2^{216193} - 1$ (Cipra 1989). The largest known prime as of 1999 is the MERSENNE PRIME $2^{6972593} - 1$.

Primes consisting of consecutive DIGITS (counting 0 as coming after 9) include 2, 3, 5, 7, 23, 67, 89, 4567, 78901, ... (Sloane's A006510).

Prime Number of Measurement

The set of numbers generated by excluding the SUMS of two or more consecutive earlier members is called

the prime numbers of measurement, or sometimes the SEGMENTED NUMBERS. The first few terms are 1, 2, 4, 5, 8, 10, 14, 15, 16, 21, ... (Sloane's A002048). Excluding two *and* three terms gives the sequence 1, 2, 4, 5, 8, 10, 12, 14, 15, 16, 19, 20, 21, ... (Sloane's A005242).

Prime Number Theorem

The theorem giving an asymptotic form for the PRIME COUNTING FUNCTION $\pi(n)$, which counts the number of PRIMES less than some INTEGER n. Legendre (1808) suggested that, for large n,

$$\pi(n) \sim \frac{n}{A \ln n + B}, \tag{1}$$

with $A = 1$ and $B = -1.08366$ (where B is sometimes called LEGENDRE'S CONSTANT), a formula which is correct in the leading term only (Nagell 1951, p. 54; Wagon 1991, pp. 28–9). In 1791, Gauss became the first to suggest instead

$$\pi(n) \sim \frac{n}{\ln n}. \tag{2}$$

Gauss later refined his estimate to

$$\pi(n) \sim \mathrm{li}(n), \tag{3}$$

where $\mathrm{li}(n)$ is the LOGARITHMIC INTEGRAL. This function has $n/\ln n$ as the leading term and has been shown to be a better estimate than $n/\ln n$ alone. The statement (3) is often known as "the" prime number theorem and was proved independently by Hadamard (1896) and de la Vallée Poussin (1896). A plot of $\pi(n)$ (lower curve) and $\mathrm{li}(n)$ is shown above for $n \leq 1000$.

For small n, it has been checked and always found that $\pi(n) < \mathrm{li(n)}$. However, Skewes proved that the first crossing of $\pi(n) < \mathrm{li}(n) = 0$ occurs before $10^{10^{10^{34}}}$ (the SKEWES NUMBER). The upper bound for the crossing has subsequently been reduced to 10^{371}. Littlewood (1914) proved that the INEQUALITY reverses infinitely often for sufficiently large n (Ball and Coxeter 1987). Lehman (1966) proved that at least 10^{500} reversals occur for numbers with 1166 or 1167 DECIMAL DIGITS.

Chebyshev put limits on the RATIO

$$\frac{7}{8} < \frac{\pi(n)}{\frac{n}{\ln n}} < \frac{9}{8} \tag{4}$$

(Landau 1927; Nagell 1951, p. 55; Landau 1974; Hardy and Wright 1979, Ch. 22; Ingham 1990; Rubinstein and Sarnak 1994; Hardy 1999, p. 27), and showed that if the LIMIT

$$\lim_{n \to \infty} \frac{\pi(n)}{\frac{n}{\ln n}} \tag{5}$$

existed, then it would be 1.

Hadamard and Vallée Poussin proved the prime number theorem by showing that the RIEMANN ZETA FUNCTION $\zeta(z)$ has no zeros OF THE FORM $1 + it$, in the sense that no deeper properties of $\zeta(s)$ are required for the proof (Smith 1994, p. 128; Hardy 1999, pp. 58–0). Wiener (1951) allowed this somewhat vague statement to be interpreted literally (Hardy 1999, pp. 34 and 46), and this proof was simplified by Landau (1932) and Bochner (1933).

Hadamard's proof depends on the simple trigonometric inequality

$$3 + 4 \cos \theta + \cos(2\theta) = 2(1 + \cos \theta)^2 \geq 0 \tag{6}$$

(Hardy 1999, p. 58). Vallée Poussin (1899) showed that

$$\pi(x) = \mathrm{li}(x) + \mathcal{O}\left(\frac{x}{\ln x}\, e^{-a\sqrt{\ln x}}\right) \tag{7}$$

for some constant a (Knuth 1997, p. 381), where $\mathcal{O}(x)$ is ASYMPTOTIC NOTATION. A simplified proof was found by Erdos (1949) and Selberg (1950) (Ball and Coxeter 1987, p. 63), although an unfortunate priority dispute over the joint work marred the otherwise beautiful proof (Hoffman 1998, pp. 39–1). An elementary proof of the prime number theorem, following Selberg, is the final section in Nagell's 1951 textbook.

The error term in (7) has subsequently improved to

$$\pi(x) = \mathrm{li}(x) + \mathcal{O}\left(x \exp\left(-\frac{A(\ln x)^{3/5}}{(\ln \ln x)^{1/5}}\right)\right) \tag{8}$$

(Walfisz 1963; Riesel 1994, p. 56; Knuth 1997, p. 382). Ingham (1930) proved the prime number

theorem using the identity of Ramanujan

$$\sum_{n=1}^{\infty} \frac{\sigma_a(n)\sigma_b(n)}{n^s} = \frac{\zeta(s)\zeta(s-a)\zeta(s-b)\zeta(s-a-b)}{\zeta(2s-a-b)}, \quad (9)$$

where $\sigma_a(n)$ is the DIVISOR FUNCTION (Hardy 1999, pp. 59–0).

Riemann estimated the PRIME COUNTING FUNCTION with

$$\pi(n) \sim \ln(n) - \tfrac{1}{2}\,\mathrm{li}(n^{1/2}), \quad (10)$$

which is a better approximation than $\mathrm{li}(n)$ for $n < 10^7$. Riemann (1859) also suggested the RIEMANN FUNCTION

$$R(x) = \sum_{n=1}^{\infty} \frac{\mu(n)}{n}\,\mathrm{li}(x^{1/n}), \quad (11)$$

where μ is the MÖBIUS FUNCTION (Wagon 1991, p. 29). An even better approximation for small n (by a factor of 10 for $n < 10^9$) is the GRAM SERIES.

The prime number theorem is equivalent to either

$$\lim_{x\to\infty} \frac{\theta(x)}{x} = 1 \quad (12)$$

or

$$\lim_{x\to\infty} \frac{\psi(x)}{x} = 1, \quad (13)$$

where θ and $\psi(x)$ are the CHEBYSHEV FUNCTIONS. Chebyshev showed that the only possible limit of these expressions was 1, but was not able to prove existence of the limit (Hardy 1999, p. 28).

The RIEMANN HYPOTHESIS is equivalent to the assertion that

$$|\mathrm{Li}(x) - \pi(x)| \leq c\sqrt{x}\,\ln x \quad (14)$$

for some value of c (Ingham 1990, p. 83; Landau 1974, pp. 378–88; Ball and Coxeter 1987; Hardy 1999, p. 26). Some limits obtained without assuming the RIEMANN HYPOTHESIS are

$$\pi(x) = \mathrm{Li}(x) + \mathcal{O}[xe^{-\ln x^{1/2}/15}] \quad (15)$$

$$\pi(x) = \mathrm{Li}(x) + \mathcal{O}\left[xe^{-0.009(\ln x)^{3/5}/(\ln \ln x)^{1/5}}\right]. \quad (16)$$

Ramanujan showed that for sufficiently large x,

$$\pi^2(x) < \frac{ex}{\ln x}\,\pi\left(\frac{x}{e}\right). \quad (17)$$

The largest known PRIME for which the inequality fails is 38,358,837,677 (Berndt 1994, pp. 112–13). The related inequality

$$\mathrm{Li}^2(x) < \frac{ex}{\ln x}\,\mathrm{Li}\left(\frac{x}{e}\right) \quad (18)$$

is true for $x \geq 2418$ (Berndt 1994, p. 114).

Prime Pairs

TWIN PRIMES

Prime Partition

A prime partition of a POSITIVE INTEGER $n \geq 2$ is a set of PRIMES p_i which sum to n. For example, there are three prime partitions of 7 since

$$7 = 7 = 2 + 5 = 2 + 2 + 3.$$

The number of prime partitions of $n = 2, 3, \ldots$ are 1, 1, 1, 2, 2, 3, 3, 4, 5, 6, 7, 9, 10, 12, 14, 17, 19, 23, 26, ... (Sloane's A000607). If $a_n = 1$ for n prime and $a_n = 0$ for n composite, then the EULER TRANSFORM b_n gives the number of partitions of n into prime parts (Sloane and Plouffe 1995, p. 21).

The minimum number of primes needed to sum to $n = 2, 3, \ldots$ are 1, 1, 2, 1, 2, 1, 2, 2, 2, 1, 2, 1, 2, 2, 2, 1, 2, ... (Sloane's A051034). The maximum number of primes needed to sum to n is just $\lfloor n/2 \rfloor$, 0, 0, 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, 6, 6, 7, 7, ... (Sloane's A004526), corresponding to a representation in terms of all 2s for an even number or one 3 and the rest 2s for an odd number.

The numbers which can be represented by a single prime are obviously the primes themselves. Composite numbers which can be REPRESENTED AS the sum of two primes are 4, 6, 8, 9, 10, 12, 14, 15, 16, 18, 20, 21, 22, ... (Sloane's A051035), and composite numbers which are not the sum of fewer than three primes are 27, 35, 51, 57, 65, 77, 87, 93, 95, 117, 119, ..., (Sloane's A025583). The conjecture that *no* numbers require four or more primes is called the GOLDBACH CONJECTURE.

Prime Patterns Conjecture

k-TUPLE CONJECTURE

Prime Pi

PRIME COUNTING FUNCTION

Prime Polynomial

PRIME-GENERATING POLYNOMIAL

Prime Power

A PRIME or integer power of a PRIME. The first few are 2, 3, 4, 5, 7, 8, 9, 11, 13, 16, 17, 19, 23, 25, ... (Sloane's A000961). The first few prime powers with power ≥ 2 are given by 4, 8, 9, 16, 25, 27, 32, 49, 64, 81, ... (Sloane's A025475). The number of prime powers (≥ 2) up to x does not exceed

$$x^{1/2} + x^{1/3} + x^{1/4} + \ldots = \mathcal{O}\left(x^{1/2} \ln x\right)$$

(Hardy 1999, p. 27).

The following table gives prime kth powers.

k	Sloane	prime kth powers
1	A000040	2, 3, 5, 7, 11, 13, 17, 19, 23, ...
2	A001248	4, 9, 25, 49, 121, 169, 289, 361, ...
3	A030078	8, 27, 125, 343, 1331, 2197, 4913, ...
4	A030514	16, 81, 625, 2401, 14641, 28561, 83521, ...
5	A050997	32, 243, 3125, 16807, 161051, 371293, ...

Prime Power Conjecture

An Abelian planar DIFFERENCE SET of order n exists only for n a PRIME POWER. Gordon (1994) has verified it to be true for $n < 2,000,000$.

See also DIFFERENCE SET

References

Gordon, D. M. "The Prime Power Conjecture is True for $n < 2,000,000$." *Electronic J. Combinatorics* **1**, R6 1–, 1994. http://www.combinatorics.org/Volume_1/volume1.html#R6.

Prime Power Symbol

The symbol $p^e \| n$ means, for p a PRIME, that $p^e \| n$, but $p^{e+1} \nmid n$.

Prime Products

The product of primes

$$p_n\# \equiv \prod_{k=1}^{n} p_k, \quad (1)$$

with p_n the nth prime, is called the PRIMORIAL function, by analogy with the FACTORIAL function.

The EULER PRODUCT gives

$$e^{\gamma} = \lim_{n\to\infty} \frac{1}{\ln n} \prod_{k=1}^{n} \frac{1}{1-\frac{1}{p_k}}, \quad (2)$$

where γ is the EULER-MASCHERONI CONSTANT. There is also an amazing infinite product formula for primes given by

$$\prod_{k=1}^{\infty} \frac{p_k^2+1}{p_k^2-1} = \frac{5}{2}. \quad (3)$$

(Ramanujan; Le Lionnais 1983, p. 46).

Prime Quadratic Effect

Let $\pi_{m,n}(x)$ denote the number of PRIMES $\leq x$ which are congruent to n modulo m. Then one might expect that

$$\Delta(x) \equiv \pi_{4,3}(x) - \pi_{4,1}(x) \sim \tfrac{1}{2}\pi\left(x^{1/2}\right) > 0$$

(Berndt 1994). Although this is true for small numbers, Hardy and Littlewood showed that $\Delta(x)$ changes sign infinitely often. The effect was first noted by Chebyshev in 1853, and is sometimes called the CHEBYSHEV PHENOMENON. It was subsequently studied by Shanks (1959), Hudson (1980), and Bays and Hudson (1977, 1978, 1979). The effect was also noted by Ramanujan, who incorrectly claimed that $\lim_{x\to\infty} \Delta(x) = \infty$ (Berndt 1994).

The values at which $\Delta(x) = 0$ are $x = 2946$, 50378, 50380, 50382, 50392, 50414, ... (Sloane's A051024), corresponding to $\pi(x) = 26861$, 616841, 616849, 616877, 617011, ... (Sloane's A051025).

Prime Quadruplet

A PRIME CONSTELLATION of four successive PRIMES with minimal distance $(p, p+2, p+6, p+8)$. The term was coined by Paul Stäckel (1892–919; Tietze 1965, p. 19). The quadruplet (2, 3, 5, 7) has smaller

minimal distance, but it is an exceptional special case. With the exception of (5, 7, 11, 13), a prime quadruple must be OF THE FORM $(30n+11, 30n+13, 30n+17, 30n+19)$. The first few values of n which give prime quadruples are $n = 0$, 3, 6, 27, 49, 62, 69, 108, 115, ... (Sloane's A014561), and the first few values of p are 5 (the exceptional case), 11, 101, 191, 821, 1481, 1871, 2081, 3251, 3461, ... (Sloane's A007530). The number of prime quadruplets with largest member less than 10^1, 10^2, ..., are 1, 2, 5, 12, 38, 166, 899, 4768, ... (Sloane's A050258; Nicely 1999).

The asymptotic FORMULA for the frequency of prime quadruples is analogous to that for other PRIME CONSTELLATIONS,

$$P_x(p, p+2, p+6, p+8) \sim \frac{27}{2} \prod_{p \geq 5} \frac{p^3(p-4)}{(p-1)^4} \int_2^x \frac{dx}{(\ln x)^4}$$

$$= 4.151180864 \int_2^x \frac{dx}{(\ln x)^4},$$

where $c = 4.15118\ldots$ is the Hardy-Littlewood constant for prime quadruplets.

Roonguthai found the large prime quadruplets with

$$p = 10^{99} + 349781731$$

$$p = 10^{199} + 21156403891$$

$$p = 10^{299} + 140159459341$$

$$p = 10^{399} + 34993836001$$

$$p = 10^{499} + 883750143961$$

$$p = 10^{599} + 1394283756151$$

$$p = 10^{699} + 547634621251$$

(Roonguthai). Forbes found the large quadruplet with

$$p = 76912895956636885(2^{3279} - 2^{1093}) - 6 \cdot 2^{1093} - 7.$$

Prime Representation

Let $a \neq b$, A, and B denote POSITIVE INTEGERS satisfying

$$(a, b) = 1 \quad (A, B) = 1$$

(i.e., both pairs are RELATIVELY PRIME), and suppose every PRIME $p \equiv B \pmod{A}$ with $(p, 2ab) = 1$ is expressible if the form $ax^2 - by^2$ for some INTEGERS x and y. Then every PRIME q such that $q \equiv -B \pmod{A}$ and $(q, 2ab) = 1$ is expressible in the form $bX^2 - aY^2$ for some INTEGERS X and Y (Halter-Koch 1993, Williams 1991).

Prime Form	Representation
$4n+1$	x^2+y^2
$8n+1,\ 8n+3$	x^2+2y^2
$8n\pm1$	x^2-2y^2
$6n+1$	x^2+3y^2
$12n+1$	x^2-3y^2
$20n+1,\ 20n+9$	x^2+5y^2
$10n+1,\ 10n+9$	x^2-5y^2
$14n+1,\ 14n+9,\ 14n+25$	x^2+7y^2
$28n+1,\ 28n+9,\ 28n+25$	x^2-7y^2
$30n+1,\ 30n+49$	x^2+15y^2
$60n+1,\ 60n+49$	x^2-15y^2
$30n-7,\ 30n+17$	$5x^2+3y^2$
$60n-7,\ 60n+17$	$5x^2-3y^2$
$24n+1,\ 24n+7$	x^2+6y^2
$24n+1,\ 24n+19$	x^2-6y^2
$24n+5,\ 24n+11$	$2x^2+3y^2$
$24n+5,\ 24n-1$	$2x^2-3y^2$

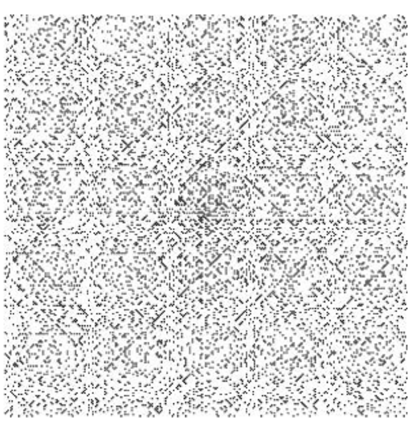
Prime Sequence

PRIME ARITHMETIC PROGRESSION, PRIME ARRAY, PRIME-GENERATING POLYNOMIAL, SIERPINSKI'S PRIME SEQUENCE THEOREM

Prime Signature

The prime signature of a positive integer n is a sorted list of exponents a_i in the PRIME FACTORIZATION



$$n = p_1^{a_1} p_2^{a_2} \cdots .$$

The prime signature of n can therefore be computed in *Mathematica* as

```
PrimeSignature[1]              :=           {1}
PrimeSignature[n_Integer?Positive] :=
   Sort[Transpose[FactorInteger[n]][[2]]]
```

See also PRIME FACTORIZATION

Prime Spiral

The numbers arranged in a SPIRAL

$$\begin{matrix} 5 & 4 & 3 \\ 6 & 1 & 2 \\ 7 & 8 & 9 \end{matrix}$$

with PRIMES indicated in black, as first drawn by S. Ulam. Unexpected patterns of diagonal lines are apparent in such a plot, as illustrated in the above 199×199 grid. M. Charpentier has written a PostScript file which can be downloaded to a printer and draws a prime spiral.

Prime String

TRUNCATABLE PRIME

Prime Subfield

The prime subfield of a FIELD F is the SUBFIELD of F generated by the multiplicative identity 1_F of F. It is isomorphic to either $\mathbb{Q}$ (if the CHARACTERISTIC is 0), or the FINITE FIELD $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ (if the CHARACTERISTIC is p).

See also SUBFIELD

Prime Sum

$$60n - 7,\ 60n + 17$$

Let

$$5x^2 - 3y^2$$

be the sum of the first n PRIMES. The first few terms are 2, 5, 10, 17, 28, 41, 58, 77, ... (Sloane's A007504). Bach and Shallit (1996) show that

$$24n + 1,\ 24n + 7$$

and provide a general technique for estimating such sums.

The first few values of n such that x^2+6y^2 are 1, 23, 53, 853, 11869, 117267, 339615, 3600489, 96643287, ... (Sloane's A045345). The corresponding values of $24n+1$, $24n+19$ are 2, 874, 5830, 2615298, 712377380, 86810649294, 794712005370, 105784534314378, 92542301212047102, ... (Sloane's A050247; Rivera), and the values of x^2-6y^2 are 2, 38, 110, 3066, 60020, 740282, 2340038, 29380602, 957565746, ... (Sloane's A050248; Rivera).

Prime Sums

Let

$$\sum(n) \equiv \sum_{i=1}^{n} p_i \tag{1}$$

be the sum of the first n PRIMES (i.e., the sum analog of the PRIMORIAL function). The first few terms are 2, 5, 10, 17, 28, 41, 58, 77, ... (Sloane's A007504). Bach and Shallit (1996) show that

$$\sum(n) \sim \frac{n^2}{2\log n}, \tag{2}$$

and provide a general technique for estimating such sums.

The first few values of n such that $n|\Sigma(n)$ are 1, 23, 53, 853, 11869, 117267, 339615, 3600489, 96643287, ... (Sloane's A045345). The corresponding values of $\Sigma(n)$ are 2, 874, 5830, 2615298, 712377380, 86810649294, 794712005370, 105784534314378, 92542301212047102, ... (Sloane's A050247; Rivera), and the values of $n/\Sigma(n)$ are 2, 38, 110, 3066, 60020, 740282, 2340038, 29380602, 957565746, ... (Sloane's A050248; Rivera).

In 1737, Euler showed that the sum of the reciprocals of the primes diverges

$$\sum_{k=1}^{\infty} \frac{1}{p_k} = \infty \tag{3}$$

(Nagell 1951, p. 59; Hardy and Wright 1979, pp. 17 and 22), although it does so very slowly. The sum exceeds 1, 2, 3, ... after 3, 59, 361139, ... (Sloane's A046024) primes, and its asymptotic equation is

$$\sum_{\substack{p=2 \\ p \text{ prime}}}^{x} \frac{1}{p} = \ln\ln x + B_1 + o(1), \tag{4}$$

where B_1 is MERTENS CONSTANT (Hardy and Wright 1979, p. 351). Dirichlet showed the even stronger result that

$$\sum_{\substack{\text{prime } p\equiv b \pmod a \\ (a,\, b)=1}} \frac{1}{p} = \infty \tag{5}$$

(Davenport 1980, p. 34). Despite the divergence of the sum of reciprocal primes, the ALTERNATING SERIES

$$\sum_{k=1}^{\infty} \frac{(-1)^k}{p_k} \approx -0.2696065 \tag{6}$$

converges (Robinson and Potter 1971, Finch), but it is not known if the sum

$$\sum_{k=1}^{\infty} (-1)^k \frac{k}{p_k} \tag{7}$$

does (Guy 1994, p. 203; Erdos 1998; Finch).

There are also classes of sums of reciprocal primes with sign determined by congruences on k, for example

$$\sum_{k=2}^{\infty} \frac{c_k}{p_k} \approx 0.3349813253 \tag{8}$$

where

$$c_k = \begin{cases} -1 & \text{for } pk \equiv 1 \pmod 4 \\ 1 & \text{for } pk \equiv 3 \pmod 4 \end{cases} \tag{9}$$

(Glaisher 1891b, Finch) which, is not known to converge, while

$$\sum_{k=2}^{\infty} \frac{c_k}{p_k^2} \approx 0.094619828 \tag{10}$$

does converge (Glaisher 1893, Finch). It is not known if

$$\sum_{k=1}^{\infty} \frac{d_k}{p_k} \approx 0.6419448385 \qquad (11)$$

converges, where

$$d_k = \begin{cases} -1 & \text{for } pk \equiv 1 \pmod 3 \\ 1 & \text{for } pk \equiv 2 \pmod 3 \\ 0 & \text{for } pk \equiv 0 \pmod 3 \end{cases} \qquad (12)$$

(Glaisher 1891c, Finch).

Although $\Sigma\, 1/p$ diverges, Brun (1919) showed that

$$\sum_{\substack{p \\ p+2 \ \text{prime}}} \frac{1}{p} = B < \infty, \qquad (13)$$

where B is BRUN'S CONSTANT. The function defined by

$$P(n) \equiv \sum_{p=1}^{\infty} \frac{1}{p_k^n} \qquad (14)$$

taken over the primes converges for $n > 1$ and is a generalization of the RIEMANN ZETA FUNCTION known as the PRIME ZETA FUNCTION.

A rapidly converging series for the MERTENS CONSTANT

$$B_1 = \gamma + \sum_{k=1}^{\infty} \left[\ln(1 - p_k^{-1}) + \frac{1}{p_k} \right] \approx 0.2614972128 \qquad (15)$$

is given by

$$B_1 = \gamma + \sum_{m=2}^{\infty} \frac{\mu(m)}{m} \ln[\zeta(m)], \qquad (16)$$

where γ is the EULER-MASCHERONI CONSTANT, $\zeta(n)$ is the RIEMANN ZETA FUNCTION, and $\mu(n)$ is the MÖBIUS FUNCTION (Flajolet and Vardi 1996, Schroeder 1997, Knuth 1998). A similar formula gives the sum

$$\sum_{k=1}^{\infty} \frac{1}{p_k^2} \sum_{k=1}^{\infty} \frac{\mu(k)}{k} \ln(\zeta(2k)) \approx 0.45224742 \qquad (17)$$

The sum

$$\sum_{k=1}^{\infty} \frac{1}{(p_k - 1)^2} \approx 1.3750649947 \qquad (18)$$

is also finite (Glaisher 1891a; Cohen; Finch).

Some curious sums satisfied by primes p include

$$\sum_{k=1}^{p-1} \left\lfloor \frac{k^3}{p} \right\rfloor = \frac{(p-2)(p-1)(p+1)}{4} \qquad (19)$$

$$\sum_{k=1}^{(p-1)(p-2)} \left\lfloor (k_p)^{1/3} \right\rfloor = \tfrac{1}{4}(3p-5)(p-2)(p-1) \qquad (20)$$

(Doster 1993),

$$\sum_{k=1}^{\infty} x^k \ln k = \sum_{p \ \text{prime}} \sum_{k=1}^{\infty} \frac{x^{p^k}}{1 - x^{p^k}}, \qquad (21)$$

and

$$\sum_{k=1}^{\infty} (-1)^{k-1} e^{-kx} \ln k = -\ln 2 \sum_{k=1}^{\infty} \frac{1}{e^{2^k x} - 1} + \sum_{\substack{p \ \text{an} \\ \text{odd prime}}} \ln p \sum_{k=1}^{\infty} \frac{1}{e^{p^k x} + 1} \qquad (22)$$

(Berndt 1994, p. 114).

Prime Theta Function

CHEBYSHEV FUNCTIONS

Prime Triangle

A triangle with rows containing the numbers $\{1, 2, \ldots, n\}$ that begins with 1, ends with n, and such that the SUM of each two consecutive entries being a PRIME. Rows 2 to 6 are unique,

$$
\begin{array}{c}
*\\
1\quad 2\\
1\quad 2\quad 3\\
1\quad 2\quad 3\quad 4\\
1\quad 4\quad 3\quad 2\quad 5\\
1\quad 4\quad 3\quad 2\quad 5\quad 6
\end{array}
$$

(Sloane's A051237) but there are multiple possibilities starting with row 7. For example, the two possibilities for row 7 are $\{1, 4, 3, 2, 5, 6, 7, \}$ and $\{1, 6, 5, 2, 3, 4, 7\}$. The number of possible rows ending with $n = 1, 2, \ldots$, are 0, 1, 1, 1, 1, 1, 2, 4, 7, 24, 80, ... (Sloane's A036440).

Prime Triplet

A prime triplet is a PRIME CONSTELLATION OF THE FORM $(p, p+2, p+6)$, $(p, p+4, p+6)$, etc. Hardy and Wright (1979, p. 5) conjecture, and it seems almost certain to be true, that there are infinitely many prime triplets OF THE FORM $(p, p+2, p+6)$ and $(p, p+4, p+6)$.

Triplet	Sloane	First Member
$(p, p+2, p+6)$	Sloane's A022004	5, 11, 17, 41, 101, 107, ...
$(p, p+2, p+8)$	Sloane's A046134	3, 5, 11, 29, 59, 71, 101, ...
$(p, p+2, p+12)$	Sloane's A046135	5, 11, 17, 29, 41, 59, 71, ...
$(p, p+4, p+6)$	Sloane's A022005	7, 13, 37, 67, 97, 103, ...
$(p, p+4, p+10)$	Sloane's A046136	3, 7, 13, 19, 37, 43, 79, ...
$(p, p+4, p+12)$	Sloane's A046317	7, 19, 67, 97, 127, 229, ...
$(p, p+6, p+8)$	Sloane's A046138	5, 11, 23, 53, 101, 131, ...
$(p, p+6, p+10)$	Sloane's A046139	7, 13, 31, 37, 61, 73, 97, ...
$(p, p+6, p+12)$	Sloane's A046140	5, 7, 11, 17, 31, 41, 47, ...
$(p, p+8, p+12)$	Sloane's A046141	5, 11, 29, 59, 71, 89, 101, ...

Prime Unit

1 and -1 are the only INTEGERS which divide every INTEGER. They are therefore called the prime units.

See also INTEGER, PRIME NUMBER, UNIT

Prime Zeta Function

The prime zeta function

$$P(n) \equiv \sum_p \frac{1}{p^n}, \tag{1}$$

where the sum is taken over PRIMES is a generalization of the RIEMANN ZETA FUNCTION

$$\zeta(n) \equiv \sum_{k=1} \frac{1}{k^n}, \tag{2}$$

where the sum is over *all* integers. The prime zeta function can be expressed in terms of the RIEMANN ZETA FUNCTION by

$$\ln \zeta(n) = -\sum_{p \geq 2} \ln(1 - p^{-n}) = \sum_{p \geq 2} \sum_{k=1}^{\infty} \frac{p^{-kn}}{k}$$

$$= \sum_{k=1}^{\infty} \frac{1}{k} \sum_{p \geq 2} p^{-kn} = \sum_{k=1}^{\infty} \frac{P(kn)}{k}. \tag{3}$$

Inverting then gives

$$P(n) = \sum_{k=1}^{\infty} \frac{\mu(k)}{k} \ln \zeta(kn), \tag{4}$$

where $\mu(k)$ is the MÖBIUS FUNCTION (Cohen 2000). $P(1)$, The analog of the HARMONIC SERIES, diverges, but convergence of the series for $n > 1$ is quadratic.

ARTIN'S CONSTANT C_{Artin} is connected with $P(n)$ by

$$\ln C_{\text{Artin}} = -\sum_{n=2}^{\infty} \frac{(\mu_n - 1)P(n)}{n}, \tag{5}$$

where

$$u_n = u_{n-1} + u_{n-2} \tag{6}$$

with $u_1 = 1$, $u_2 = 3$ (Ribenboim 1998, Gourdon and Sebah).

The values of $P(n)$ for the first few integers n starting with two are

$$P(2) \approx 0.452247 \tag{7}$$

$$P(3) \approx 0.174763 \tag{8}$$

$$P(4) \approx 0.0769931 \tag{9}$$

$$P(5) \approx 0.035755. \tag{10}$$

Merrifield (1881) computed $P(n)$ for n up to 35 to 15 digits, and Liénard (1948) computed $P(n)$ up to $n = 167$ to 50 digits (Ribenboim 1996). Gourdon gives values to 60 digits for $2 \geq n \leq 8$.

Primefree Sequence

A sequence whose terms are never prime. Graham proved that there exist primefree sequences generated by Fibonacci-like recurrences OF THE FORM

$$a_n = a_{n-1} + a_{n-2}$$

for $(a_1, a_2) = 1$, i.e., RELATIVELY PRIME. However, the purported example given by Hoffman (1998, p. 159) in fact contains prime terms for $n = 138$, 163, 190, 523, ...

References

Hoffman, P. *The Man Who Loved Only Numbers: The Story of Paul Erdos and the Search for Mathematical Truth.* New York: Hyperion, 1998.

Prime-Generating Polynomial

Legendre showed that there is no RATIONAL algebraic function which always gives PRIMES. In 1752, Goldbach showed that no POLYNOMIAL with INTEGER COEFFICIENTS can give a PRIME for all integer values (Nagell 1951, p. 65; Hardy and Wright 1979, pp. 18 and 22). However, there exists a POLYNOMIAL in 10 variables with INTEGER COEFFICIENTS such that the set of PRIMES equals the set of POSITIVE values of this POLYNOMIAL obtained as the variables run through all NONNEGATIVE INTEGERS, although it is really a set of DIOPHANTINE EQUATIONS in disguise (Ribenboim 1991).

Polynomial	Range	Sloane	Reference
$36n^2 - 810n + 2753$	[0, 44]	A050268	Fung and Ruby
$47n^2 - 1701n + 10181$	[0, 42]	A050267	Fung and Ruby

n^2+n+41	[0, 39]	A005846	Euler
$2n^2+29$	[0, 28]	A033542	Legendre
n^2+n+17	[0, 15]	A033541	Legendre
$4n^2+4n+59$	[0, 13]	A048988	
$2n^2+11$	[0, 10]	A050265	
n^3+n^2+17	[0, 10]	A050266	

The above table gives some low-order polynomials which generate only PRIMES for the first few NONNEGATIVE values (Mollin and Williams 1990). The best-known of these formulas is that due to Euler (Euler 1772; Nagell 1951, p. 65; Gardner 1984, p. 83; Ball and Coxeter 1987),

$$n^2+n+41. \tag{1}$$

which gives distinct primes for the 40 consecutive integers $n=0$ to 39. (n^2-n+41 gives the same 40 primes for $n=1$ to 40.) By transforming the formula to

$$n^2-79n+1601=(n-40)^2+(n-40)+41, \tag{2}$$

primes are obtained for 80 consecutive integers, corresponding to the 40 primes given by the above formula taken twice each (Hardy and Wright 1979, p. 18).

Le Lionnais (1983) has christened numbers p such that the Euler-like polynomial

$$n^2+n+p \tag{3}$$

is PRIME for $n=0, 1, ..., p-2$ as LUCKY NUMBERS OF EULER (where the case $p=41$ corresponds to Euler's formula). Rabinowitz (1913) showed that for a PRIME $p>0$, Euler's polynomial represents a PRIME for $n\in[0, p-2]$ (excluding the trivial case $p=3$) IFF the FIELD $\mathbb{Q}(\sqrt{1-4p})$ has CLASS NUMBER $h=1$ (Rabinowitz 1913, Le Lionnais 1983, Conway and Guy 1996). As established by Stark (1967), there are only nine numbers $-d$ such that $h(-d)=1$ (the HEEGNER NUMBERS -2, -3, -7, -11, -19, -43, -67, and -163), and of these, only 7, 11, 19, 43, 67, and 163 are of the required form. Therefore, the only LUCKY NUMBERS OF EULER are 2, 3, 5, 11, 17, and 41 (le Lionnais 1983, Sloane's A014556), and there does not exist a better prime-generating polynomial of Euler's form. The connection between the numbers 163 and 43 and some of the prime-rich polynomials listed above can be seen explicitly by writing

$$x^2+x+41=\left(x+\tfrac{1}{2}\right)^2+\tfrac{163}{4} \tag{4}$$

$$x^2+x+11=\left(x+\tfrac{1}{2}\right)^2+\tfrac{43}{4}, \tag{5}$$

etc.

Euler also considered quadratics OF THE FORM

$$2x^2+p \tag{6}$$

and showed this gives PRIMES for $x\in[0, p-1]$ for PRIME $p>0$ IFF $\mathbb{Q}(\sqrt{-2p})$ has CLASS NUMBER 2, which permits only $p=3$, 5, 11, and 29. Baker (1971) and Stark (1971) showed that there are no such FIELDS for $p>29$. Similar results have been found for POLYNOMIALS OF THE FORM

$$px^2+px+n \tag{7}$$

(Hendy 1974).

Primequad

PRIME QUADRUPLET

Primes

The set of PRIME NUMBERS, sometimes denoted $\mathbb{P}$, and implemented in *Mathematica* as `Primes`. In *Mathematica*, a quantity can be tested to determine if it is in the domain of prime numbers using `Element[`n`, Primes]`, which is equivalent to `PrimeQ[`n`]`.

See also PRIME NUMBER

Primitive Abundant Number

An ABUNDANT NUMBER for which all PROPER DIVISORS are DEFICIENT is called a primitive abundant number (Guy 1994, p. 46). The first few ODD primitive abundant numbers are 945, 1575, 2205, 3465, ... (Sloane's A006038).

Primitive Character

See also CHARACTER (NUMBER THEORY)

Primitive Element

Given algebraic numbers a_1, ..., a_n it is always possible to find a single ALGEBRAIC NUMBER b such that each of a_1, ..., a_n can be expressed as a polynomial in b with rational coefficients. The number b is then called a primitive element of the EXTENSION FIELD $\mathbb{Q}(a_1, \ldots, a_n)/\mathbb{Q}$. Stated differently, an ALGEBRAIC NUMBER b is a primitive element of $\mathbb{Q}(a_1, \ldots, a_n)/\mathbb{Q}$ IFF $\mathbb{Q}(a_1, \ldots, a_n) = \mathbb{Q}(b)$. Primitive elements are implemented in *Mathematica* as `PrimitiveElement[`z`, {`$a1$`, ..., `an`}]` in the *Mathematica* add-on package `NumberTheory`PrimitiveElement`` (which can be loaded with the command `<<NumberTheory``).

For example, a primitive element of $\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$ is given by $b = \sqrt{2} + \sqrt{3}$, with

$$\sqrt{2} = \tfrac{1}{2}b(b^2 - 9)$$
$$\sqrt{3} = \tfrac{1}{2}b(11 - b^2).$$

Primitive Function

INTEGRAL

Primitive Group

A GROUP that has a PRIMITIVE GROUP ACTION.

See also PRIMITIVE GROUP ACTION

Primitive Group Action

A primitive group action is TRANSITIVE and it has no nontrivial BLOCKS. A TRANSITIVE GROUP ACTION that is not primitive is called imprimitive. A group that has a primitive group action is called a PRIMITIVE GROUP.

See also BLOCK (GROUP ACTION), GROUP, PRIMITIVE GROUP, SOCLE, TRANSITIVE GROUP, TRANSITIVE GROUP ACTION

References

Dixon, J. and Mortimer, B. *Permutation Groups.* New York: Springer-Verlag, 1996.

Primitive Polynomial

A polynomial which generates all elements of an EXTENSION FIELD from a base field is called a primitive polynomial. Primitive polynomials are also IRREDUCIBLE POLYNOMIALS. For any PRIME or PRIME POWER q and any POSITIVE INTEGER n, there exists a primitive polynomial of order n over GF(q). There are $\phi(q^n - 1)/n$ primitive polynomials over GF(q), where $\phi(n)$ is the TOTIENT FUNCTION.

Polynomials over the FINITE FIELD GF(2) (i.e., with coefficients either 0 or 1) are primitive if they have ORDER $2^n - 1$, where "order" is used in the specific sense of a HAUPT-EXPONENT or ORDER of a modulo. For example, $x^2 + x + 1 = (x^2 + x + 1)(x + 1) = x^3 + 1$ has order 3, and is therefore primitive (Ruskey). Amazingly, primitive polynomials over GF(2) define a RECURRENCE RELATION which can be used to obtain

a new RANDOM bit from the n preceding ones. The numbers of primitive polynomials over GF(2) for $n = 1, 2, \ldots$ are 1, 1, 2, 2, 6, 6, 18, 16, 48, ... (Sloane's A011260). The following table lists the primitive polynomials (mod 2) of orders 1 through 5.

n	primitive polynomials
1	x
2	$1+x+x^2$
3	$1+x+x^3$, $1+x^2+x^3$
4	$1+x+x^4$, $1+x^3+x^4$
5	$1+x^2+x^5$, $1+x+x^2+x^3+x^5$, $1+x^3+x^5$, $1+x+x^3+x^4+x^5$, $1+x^2+x^3+x^4+x^5$, $1+x+x^2+x^4+x^5$

Primitive Polytope

A POLYTOPE in n-D Euclidean space $\mathbb{R}^n$ whose vertices are integer lattice points but which does not contain any other lattice points in its interior or on its boundary (Khan 1999).

See also HOWE'S THEOREM, POLYTOPE

References

Khan, M. R. "A Counting Formula for Primitive Tetrahedra in Z^3." *Amer. Math. Monthly* **106**, 525–33, 1999.

Primitive Prime Factor

If $n \geq 1$ is the smallest INTEGER such that $P|a^n - b^n$ (or $a^n + b^n$), then p is a primitive prime factor.

See also PRIME FACTORS, PRIMITIVE ROOT

Primitive Pseudoperfect Number

PRIMITIVE SEMIPERFECT NUMBER

Primitive Recursive Function

For-loops (which have a fixed iteration limit) are a special case of while-loops. A function which can be implemented using only for-loops is called primitive recursive. (In contrast, a COMPUTABLE FUNCTION can be coded using a combination of for- and while-loops, or while-loops only.)

The ACKERMANN FUNCTION is the simplest example of a WELL DEFINED TOTAL FUNCTION which is COMPUTABLE but not primitive recursive, providing a counterexample to the belief in the early 1900s that every COMPUTABLE FUNCTION was also primitive recursive (Dötzel 1991).

See also ACKERMANN FUNCTION, COMPUTABLE FUNCTION, TOTAL FUNCTION

References

Dötzel, G. "A Function to End All Functions." *Algorithm: Recreational Programming* **2**, 16–7, 1991.

Primitive Root

A primitive root of a PRIME p is an INTEGER g satisfying $1 \leq g \leq p-1$ such that the residue classes of $g, g^2, g^3, \ldots, g^{p-1} = 1$ are all distinct, i.e., $g \pmod p$ has ORDER $p-1$ (Ribenboim 1996, p. 22). If p is a PRIME NUMBER, then there are exactly $\phi(p-1)$ incongruent primitive roots of p (Burton 1989, p. 194).

More generally, if $(g, n) = 1$ (g and n are RELATIVELY PRIME) and g is of ORDER $\phi(n)$ modulo n, where $\phi(n)$ is the TOTIENT FUNCTION, then g is a primitive root of n (Burton 1989, p. 187). In other words, n has g as a primitive root if $g^{\phi(n)} \equiv 1 \pmod n$, but $g^k \not\equiv 1 \pmod n$ for all positive integers $k < \phi(n)$. A primitive root of a number n (but not necessarily the *smallest* primitive root for composite n) can be computed using the *Mathematica* routine `PrimitiveRoot[n]` in the *Mathematica* add-on package `NumberTheory`NumberTheoryFunctions`` (which can be loaded with the command `<<NumberTheory``).

If n has a primitive root, then it has exactly $\phi(\phi(n))$ of them (Burton 1989, p. 188). For $n = 1, 2, \ldots$, the first few values of $\phi(\phi(n))$ are 1, 1, 1, 1, 2, 1, 2, 2, 2, 2, 4, 2, 4, 2, 4, 4, 8, ... (Sloane's A010554). n has a primitive root if it is OF THE FORM 2, 4, a power p^a, or twice a power $2p^a$, where p is an ODD PRIME and $a \geq 1$ (Burton 1989, p. 204). The first few n for which primitive roots exist are 2, 3, 4, 5, 6, 7, 9, 10, 11, 13, 14, 17, 18, 19, 22, ... (Sloane's A033948), so the number of primitive root of order n for $n = 1, 2, \ldots$ are 0, 1, 1, 1, 2, 1, 2, 0, 2, 2, 4, 0, 4, ... (Sloane's A046144).

The smallest primitive roots for the first few primes p are 1, 2, 2, 3, 2, 2, 3, 2, 5, 2, 3, 2, 6, 3, 5, 2, 2, 2, ... (Sloane's A001918). Here is table of the primitive roots for the first few n for which a primitive root exists (Sloane's A046147).

n	$g(n)$
2	1
3	2
4	3
5	2, 3
6	5
7	3, 5
9	2, 5
10	3, 7
11	2, 6, 7, 8
13	2, 6, 7, 11

The largest primitive roots for $n = 1, 2, \ldots$, are 0, 1, 2, 3, 3, 5, 5, 0, 5, 7, 8, 0, 11, ... (Sloane's A046146). The smallest primitive roots for the first few INTEGERS n are given in the following table (Sloane's A046145), which omits n when $g(n)$ does not exist.

2	1	38	3	94	5	158	3

Let p be any ODD PRIME $k \geq 1$, and let

$$s \equiv \sum_{j=1}^{p-1} j^k. \tag{1}$$

Then

$$s = \begin{cases} -1 \pmod{p} & \text{for } p-1 \mid k \\ 0 \pmod{p} & \text{for } p-1 \nmid k \end{cases} \tag{2}$$

(Ribenboim 1996, pp. 22–3). For numbers m with primitive roots, all y satisfying $(p, y) = 1$ are representable as

$$y \equiv g^t \pmod{m}, \tag{3}$$

where $t = 0, 1, \ldots, \phi(m) - 1$, t is known as the index, and y is an INTEGER. Kearnes (1984) showed that for any POSITIVE INTEGER m, there exist infinitely many PRIMES p such that

$$m < g_p < p - m. \tag{4}$$

Call the least primitive root g_p. Burgess (1962) proved that

$$g_p \leq C p^{1/4+\epsilon} \tag{5}$$

for C and ϵ POSITIVE constants and p sufficiently large (Ribenboim 1996, p. 24).

Matthews (1976) obtained a formula for the "two-dimensional" Artin's constants for the set of primes for which m and n are both primitive roots.

Primitive Semiperfect Number

A SEMIPERFECT NUMBER for which none of its PROPER DIVISORS are pseudoperfect (Guy 1994, p. 46). The first few are 6, 20, 28, 88, 104, 272, ... (Sloane's A006036). Primitive semiperfect numbers are also called primitive pseudoperfect numbers (Guy 1994, p. 46) or irreducible semiperfect numbers. There are infinitely many primitive pseudoperfect numbers which are not HARMONIC DIVISOR NUMBERS, and infinitely many ODD primitive semiperfect numbers.

See also HARMONIC DIVISOR NUMBER, PRIMARY PSEUDOPERFECT NUMBER, SEMIPERFECT NUMBER

Primitive Sequence

A SEQUENCE in which no term DIVIDES any other. Let S_n be the set $\{1, \ldots, n\}$, then the number of primitive subsets of S_n are 2, 3, 5, 7, 13, 17, 33, 45, 73, 103, 205, 253, ... (Sloane's A051026). For example, the five primitive sequences in S_4 are $\emptyset$, $\{1\}$, $\{2\}$, $\{2, 3\}$, $\{3\}$, $\{3, 4\}$, and $\{4\}$.

Primorial

For the nth PRIME p_n,

$$\text{primorial}(p_n) = p_n\# \equiv \prod_{j=1}^{n} p_j.$$

The values of $p_n\#$ for $n = 1, 2, ...,$ are 2, 6, 30, 210, 2310, 30030, 510510, ... (Sloane's A002110).

The primorial satisfies the unexpected limit

$$\lim_{n\to\infty} (p_n\#)^{1/p_n} = e$$

(Ruiz 1997), where E is the usual base of the NATURAL LOGARITHM.

$p\# - 1$ is PRIME for PRIMES $p = 3$, 5, 11, 41, 89, 317, 337, 991, 1873, 2053, 2377, 4093, 4297, ... (Sloane's A006794; Guy 1994), or p_n for $n = 2$, 3, 5, 13, 24, 66, 68, 167, 287, 310, 352, 564, 590, ..., up to a search limit of $p = 25000$ (Caldwell 1995).

$p\# + 1$ is known to be PRIME for the PRIMES $p = 2$, 3, 5, 7, 11, 31, 379, 1019, 1021, 2657, 3229, 4547, 4787, 11549, ... (Sloane's A005234; Guy 1994, Mudge 1997), or p_n for $n = 1$, 2, 3, 4, 5, 11, 75, 171, 172, 384, 457, 616, 643, 1391, ... (Sloane's A014545), up to a search limit of $p = 25000$ (Caldwell 1995). The numbers $E_n = p_n\# + 1$ for p_n the nth prime are known as EUCLID NUMBERS. It is not known if there are an infinite number of PRIMES for which $p\# + 1$ is PRIME or COMPOSITE (Ribenboim 1989, Guy 1994).

Prince Rupert's Cube

The largest CUBE which can be made to pass through a given CUBE. (In other words, the CUBE having a side length equal to the side length of the largest HOLE of a SQUARE CROSS SECTION which can be cut through a unit CUBE without splitting it into two pieces.) Prince Rupert's cube cuts a HOLE of the shape indicated in the above illustration (Wells 1991).

The Prince Rupert's cube has side length $3\sqrt{2}/4 \approx 1.0606601\ldots$, and any CUBE this size or smaller can be made to pass through the original CUBE.

Principal Bundle

A principal bundle is a special case of a FIBER BUNDLE where the FIBER is a GROUP G. More specifically, G is usually a LIE GROUP. A principal bundle is a TOTAL SPACE E along with a SURJECTIVE map $\pi : E \to B$ to a BASE MANIFOLD B. Any FIBER $\pi^{-1}(b)$ is a space ISOMORPHIC to G. More specifically, G acts FREELY without FIXED POINT on the fibers, and this makes a fiber into a HOMOGENEOUS SPACE. For example, in the case of a CIRCLE BUNDLE (i.e., when $G = S^1 = \{e^{it}\}$), the fibers are circles, which can be rotated, although no point in particular corresponds to the identity. Near every point, the fibers can be given the GROUP structure of G in the fibers over a NEIGHBORHOOD $b \in B$ by choosing an element in each fiber to be the IDENTITY ELEMENT. However, the fibers cannot be given a group structure globally, except in the case of a TRIVIAL BUNDLE.

An important principal bundle is the FRAME BUNDLE on a RIEMANNIAN MANIFOLD. This bundle reflects the different ways to give an ORTHONORMAL BASIS for TANGENT VECTORS.

circle bundle on the sphere

Consider all of the unit tangent vectors on the sphere. This is a principal bundle E on the SPHERE with FIBER the circle $\mathbb{S}^1$. Every TANGENT VECTOR projects to its base point in $\mathbb{S}^2$, giving the map $\pi : E \to \mathbb{S}^2$. Over every point in $\mathbb{S}^2$, there is a circle of unit tangent vectors. No particular vector is singled out as the identity, but the group $\mathbb{S}^1$ of rotations acts freely without fixed point on the fibers.

In a similar way, any fiber bundle corresponds to a principal bundle where the group (of the principal bundle) is the group of isomorphisms of the fiber (of the fiber bundle). Given a principal bundle $\pi : E \to B$ and an action of G on a space F, which could be a REPRESENTATION, this can be reversed to give an ASSOCIATED FIBER BUNDLE.

A TRIVIALIZATION of a principal bundle, an open set U in B such that the bundle over U, $\pi^{-1}(U)$, is expressed as $U \times G$, has the property that the group G acts on the left. That is, g acts on (b, h) by (b, gh). Tracing through these definitions, it is not hard to see that the TRANSITION FUNCTIONS take values in G, acting on the fibers by right multiplication. This way the action of G on a fiber is independent of coordinate chart.

Principal Curvatures

The MAXIMUM and MINIMUM of the NORMAL CURVATURE κ_1 and κ_2 at a given point on a surface are called the principal curvatures. The principal curvatures measure the MAXIMUM and MINIMUM bending of a REGULAR SURFACE at each point. The GAUSSIAN CURVATURE K and MEAN CURVATURE H are related to κ_1 and κ_2 by

$$K = \kappa_1 \kappa_2 \quad (1)$$

$$H = \tfrac{1}{2}(\kappa_1 + \kappa_2). \quad (2)$$

This can be written as a QUADRATIC EQUATION

$$\kappa^2 - 2H\kappa + K = 0, \quad (3)$$

which has solutions

$$\kappa_1 = H + \sqrt{H^2 - K} \quad (4)$$

$$\kappa_2 = H - \sqrt{H^2 - K}. \quad (5)$$

See also GAUSSIAN CURVATURE, MEAN CURVATURE, NORMAL CURVATURE, NORMAL SECTION, PRINCIPAL DIRECTION, PRINCIPAL RADIUS OF CURVATURE, RODRIGUES' CURVATURE FORMULA

References

Principal Curve

A curve $\boldsymbol{\alpha}$ on a REGULAR SURFACE M is a principal curve IFF the velocity $\boldsymbol{\alpha}'$ always points in a PRINCIPAL DIRECTION, i.e.,

$$S(\boldsymbol{\alpha}') = \kappa_i \boldsymbol{\alpha}',$$

where S is the SHAPE OPERATOR and κ_i is a PRINCIPAL CURVATURE. If a SURFACE OF REVOLUTION generated by a plane curve is a REGULAR SURFACE, then the MERIDIANS and PARALLELS are principal curves.

Principal Ideal

An IDEAL $\mathfrak{I}$ of a RING R is called principal if there is an element a of R such that

$$\mathfrak{I} = aR = \{ar : r \in R\}.$$

In other words, the IDEAL is generated by the element a. For example, the IDEALS $n\mathbb{Z}$ of the RING of INTEGERS $\mathbb{Z}$ are all principal, and in fact all IDEALS of $\mathbb{Z}$ are principal.

See also IDEAL, PRINCIPAL RING, RING

Principal Ideal Domain

A more common way to describe a PRINCIPAL IDEAL RING.

See also ALGEBRAIC NUMBER THEORY, PRINCIPAL IDEAL RING

Principal Ideal Ring

Principal Normal Vector

NORMAL VECTOR

Principal Part

If a function f has a POLE at z_0, then the negative power part

$$\sum_{j=-k}^{-1} a_j(z-z_0)^j \quad (1)$$

of the LAURENT SERIES of f about z_0

$$\sum_{j=-k}^{\infty} a_j(z-z_0)^j \quad (2)$$

is called the principal part of f at z_0. For example, the principal part of

$$\frac{z^2+1}{\sin(z^3)} = z^{-3}+z^{-2}+\tfrac{1}{6}z^3+\tfrac{1}{6}z^4+\ldots \quad (3)$$

is $z^{-3}+z^{-2}$ (Krantz 1999, pp. 46–7).

See also LAURENT POLYNOMIAL, LAURENT SERIES

References

Krantz, S. G. "Principal Part of a Function." §4.3.1 in *Handbook of Complex Analysis.* Boston, MA: Birkhäuser, pp. 46–8, 1999.

Principal Quintic Form

A general QUINTIC EQUATION

$$a_5x^5+a_4x^4+a_3x^3+a_2x^2+a_1x+a_0=0 \quad (1)$$

can be reduced to one OF THE FORM

$$y^5+b_2y^2+b_1y+b_0=0, \quad (2)$$

called the principal quintic form.

NEWTON'S RELATIONS for the ROOTS y_j in terms of the b_js is a linear system in the b_j, and solving for the b_js expresses them in terms of the POWER sums $s_n(y_j)$. These POWER sums can be expressed in terms of the a_js, so the b_js can be expressed in terms of the a_js. For a quintic to have no quartic or cubic term, the sums of the ROOTS and the sums of the SQUARES of the ROOTS vanish, so

$$s_1(y_j)=0 \quad (3)$$

$$s_2(y_j)=0. \quad (4)$$

Assume that the ROOTS y_j of the new quintic are related to the ROOTS x_j of the original quintic by

$$y_j=x_j^2+\alpha x_j+\beta. \quad (5)$$

Substituting this into (1) then yields two equations for α and β which can be multiplied out, simplified by using NEWTON'S RELATIONS for the POWER sums in the x_j, and finally solved. Therefore, α and β can be expressed using RADICALS in terms of the COEFFICIENTS a_j. Again by substitution into (4), we can calculate $s_3(y_j)$, $s_4(y_j)$ and $s_5(y_j)$ in terms of α and β and the x_j. By the previous solution for α and β and again by using NEWTON'S RELATIONS for the POWER sums in the x_j, we can ultimately express these POWER sums in terms of the a_j.

See also BRING QUINTIC FORM, NEWTON'S RELATIONS, QUINTIC EQUATION

Principal Radius of Curvature

At each point on a given a 2-D SURFACE, there are two "principal" RADII OF CURVATURE. The larger is denoted R_1, and the smaller R_2. The "principal directions" corresponding to the principal radii of curvature are PERPENDICULAR to one another. In other words, the surface normal planes at the point and in the principal directions are PERPENDICULAR to one another, and both are PERPENDICULAR to the surface tangent plane at the point.

See also GAUSSIAN CURVATURE, MEAN CURVATURE, RADIUS OF CURVATURE

Principal Ring

A principal ring (sometimes called a principal ideal ring) is a RING in which every IDEAL is PRINCIPAL, i.e. can be generated by a single element. Examples include the ring of integers $\mathscr{Z}$, any FIELD, and any polynomial ring in one variable over a FIELD.

Principal rings are very useful because in a principal ring, any two nonzero elements have a WELL DEFINED GREATEST COMMON DIVISOR. Furthermore each nonzero, nonunit element in a principal ring has a unique factorization into prime elements (up to unit elements).

While all EUCLIDEAN RINGS are principal rings, the converse is not true.

See also EUCLIDEAN RING, PRINCIPAL IDEAL

References

Wilson, J. C. "A Principal Ring that is Not a Euclidean Ring." *Math. Mag.* 34–8, 1973.

Principal Root of Unity

A principal nth root ω of unity is a root satisfying the equations $\omega^n=1$ and

$$\sum_{i=0}^{n-1} \omega^{ij}=0$$

for $j=1, 2, \ldots, n$. Therefore, every PRIMITIVE ROOT OF UNITY of fixed degree n over a field is a principal root of unity, although this is not in general true over rings (Bini and Pan 1994, p. 11).

Informally, the term "principal root" is often used to refer to the ROOT OF UNITY having smallest positive ARGUMENT.

See also PRIMITIVE ROOT OF UNITY, PRINCIPAL SQUARE ROOT, ROOT OF UNITY

References

Bini, D. and Pan, V. *Polynomial and Matrix Computations, Vol. 1: Fundamental Algorithms.* Boston, MA: Birkhäuser, 1994.

Principal Square Root

The unique nonnegative SQUARE ROOT of a nonnegative REAL NUMBER. For example, the principal square root of 9 is 3, although *both* -3 and 3 are square roots of 9.

The concept of principal square root cannot be extended to real negative numbers since the two square roots of a negative number cannot be distinguished until one of the two is defined as the imaginary unit, at which point $+i$ and $-i$ can then be distinguished. Since either choice is possible, there is no ambiguity in defining i as "the" square root of -1.

See also I, PRINCIPAL ROOT OF UNITY, SQUARE ROOT

Principal Value

CAUCHY PRINCIPAL VALUE

Principal Vector

A tangent vector $\mathbf{v}_{\rm p} = v_1\mathbf{x}_u + v_2\mathbf{x}_v$ is a principal vector IFF

$$\det\begin{bmatrix} v_2^2 & -v_1v_2 & v_1^2 \\ E & F & G \\ e & f & g \end{bmatrix} = 0,$$

where e, f, and g are coefficients of the first FUNDAMENTAL FORM and E, F, G of the second FUNDAMENTAL FORM.

Printer's Errors

Typesetting "errors" in which exponents or multiplication signs are omitted but the resulting expression is equivalent to the original one. Examples include

$$2^5 9^2 = 2592 \quad (1)$$

$$3^4 425 = 34425 \quad (2)$$

$$31^2 325 = 312325 \quad (3)$$

and

$$2^5 \cdot \tfrac{25}{31} = 25\tfrac{25}{31}, \quad (4)$$

where a whole number followed by a fraction is interpreted as a MIXED FRACTION (e.g., $1\frac{1}{2} = 1 + \frac{1}{2} = \frac{3}{2}$). D. Wilson computed all possible errors obtained by dropping exponents in a product for bases 2 to 15 and numbers $\leq 2^{64}$:

$$2^4 = 24_6 \quad (5)$$

$$3^3 = 33_8 \quad (6)$$

$$5^1 2^3 2^8 7^4 = 51232874_9. \quad (7)$$

Wilson also gave $11292450A0A8_{12}$ and $372B9A830000000000_{12}$, where the two digit base-b satisfies

$$p^q = pb + q \quad (8)$$

and for which there exist an infinite number of examples.

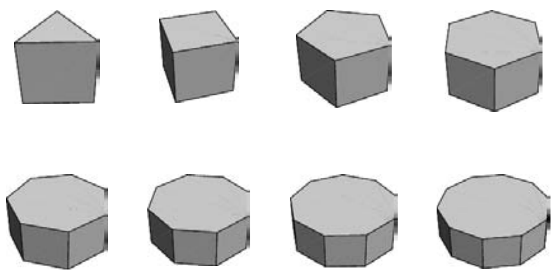
Prism



An oblique prism is a POLYHEDRON with two congruent POLYGONAL faces and all remaining faces PARALLELOGRAMS (left figure). A right prism is a prism in which the top and bottom polygons lie on top of each other so that the vertical polygons connecting their sides are not only PARALLELOGRAMS, but RECTANGLES (right figure).

The prisms have particularly simple nets, given by two oppositely-oriented n-gonal bases connected by a ribbon of n squares.

The VOLUME of a prism of height h and base area A is simply

$$V = Ah.$$

The above figure shows the first few regular right prisms, whose faces are regular n-gons. The 4-prism is simply the CUBE. The simple prisms and antiprisms include the decagonal antiprism, decagonal prism, hexagonal antiprism, hexagonal prism, octagonal antiprism, octagonal prism, pentagonal antiprism, pentagonal prism, square antiprism, and triangular prism. The DUAL POLYHEDRON of a simple (Archimedean) prism is a DIPYRAMID. The unit regular right prism has volume given by

$$V_n = 1 \cdot A_n = \tfrac{1}{4} n \cot\left(\frac{\pi}{n}\right),$$

where A_n is the AREA of the corresponding REGULAR POLYGON, and SURFACE AREA

$$S_n = 2A_n + n \cdot 1^2 = n\left[1 + \tfrac{1}{2}\cot\left(\frac{\pi}{n}\right)\right].$$

The triangular prism, square prism (cube), and hexagonal prism are all SPACE-FILLING POLYHEDRA.

Prismatoid

A POLYHEDRON having two POLYGONS in PARALLEL planes as bases and TRIANGULAR or TRAPEZOIDAL lateral faces with one side lying in one base and the opposite VERTEX or side lying in the other base. Examples include the CUBE, PYRAMIDAL FRUSTUM, RECTANGULAR PARALLELEPIPED, PRISM, and PYRAMID.

Let A_1 be the AREA of the lower base, A_2 the AREA of the upper base, M the AREA of the midsection, and h the ALTITUDE. Then

$$V = \tfrac{1}{6} h(A_1 + 4M + A_2).$$

Prisoner's Dilemma

A problem in GAME THEORY first discussed by A. Tucker. Suppose each of two prisoners A and B, who are not allowed to communicate with each other, is offered to be set free if he implicates the other. If neither implicates the other, both will receive the usual sentence. However, if the prisoners implicate each other, then both are presumed guilty and granted harsh sentences.

A DILEMMA arises in deciding the best course of action in the absence of knowledge of the other prisoner's decision. Each prisoner's best strategy would appear to be to turn the other in (since if A makes the worst-case assumption that B will turn him in, then B will walk free and A will be stuck in jail if he remains silent). However, if the prisoners turn each other in, they obtain the worst possible outcome for both.

Prizes

MATHEMATICS PRIZES

Probability

Probability is the branch of mathematics which studies the possible outcomes of given events together with their relative likelihoods and distributions. In common usage, the word "probability" is used to mean the chance that a particular event (or set of events) will occur expressed on a linear scale from 0 (impossibility) to 1 (certainty), also expressed as a PERCENTAGE between 0 and 100%. The analysis of events governed by probability is called STATISTICS.

There are several competing interpretations of the actual "meaning" of probabilities. Frequentists view probability simply as a measure of the frequency of outcomes (the more conventional interpretation), while BAYESIANS treat probability more subjectively as a statistical procedure which endeavors to estimate parameters of an underlying distribution based on the observed distribution.

A properly normalized function which assigns a probability "density" to each possible outcome within some interval is called a PROBABILITY FUNCTION, and its cumulative value (integral for a continuous distribution or sum for a discrete distribution) is called a DISTRIBUTION FUNCTION.

Probabilities are defined to obey certain assumptions, called the PROBABILITY AXIOMS. Let a SAMPLE SPACE contain the UNION ($\cup$) of all possible events E_i, so

$$S \equiv \left(\bigcup_{i=1}^{N} E_i \right), \tag{1}$$

and let E and F denote subsets of S. Further, let $F' =$ not-F be the complement of F, so that

$$F \cup F' = S. \tag{2}$$

Then the set E can be written as

$$E = E \cap S = E \cap (F \cup F') = (E \cap F) \cup (E \cap F'), \tag{3}$$

where $\cap$ denotes the intersection. Then

$$\begin{aligned} P(E) &= P(E \cap F) + P(E \cap F') - P[(E \cap F) \cap (E \cap F')] \\ &= P(E \cap F) + P(E \cap F') - P[(F \cap F') \cap (E \cap E)] \\ &= P(E \cap F) + P(E \cap F') - P(\emptyset \cap E) \\ &= P(E \cap F) + P(E \cap F') - P(\emptyset) \end{aligned}$$

$$= P(E \cap F) + P(E \cap F'), \tag{4}$$

where $\varnothing$ is the EMPTY SET.

Let $P(E|F)$ denote the CONDITIONAL PROBABILITY of E given that F has already occurred, then

$$P(E) = P(E|F)P(F) + P(E|F')P(F') \tag{5}$$

$$= P(E|F)P(F) + P(E|F')[1 - P(F)] \tag{6}$$

$$P(A \cap B) = P(A)P(B|A) \tag{7}$$

$$= P(B)P(A|B) \tag{8}$$

$$P(A' \cap B) = P(A')P(B|A') \tag{9}$$

$$P(E|F) = \frac{P(E \cap F)}{P(F)}. \tag{10}$$

The relationship

$$P(A \cap B) = P(A)P(B) \tag{11}$$

holds if A and B are independent events. A very important result states that

$$P(E \cup F) = P(E) + P(F) - P(E \cap F), \tag{12}$$

which can be generalized to

$$P\left(\bigcup_{i=1}^{n} A_i\right) = \sum_i P(A_i) - \sum_{ij}{}' P(A_i \cup A_j) + \sum_{i,j,k}{}'' P(A_i \cap A_j \cap A_k) - \ldots + (-1)^{n-1} P\left(\bigcap_{i=1}^{n} A_i\right). \tag{13}$$

See also BAYES' FORMULA, CONDITIONAL PROBABILITY, COUNTABLE ADDITIVITY PROBABILITY AXIOM, DISTRIBUTION FUNCTION, EQUALLY LIKELY OUTCOMES DISTRIBUTION, INDEPENDENT STATISTICS, LIKELIHOOD, PROBABILITY AXIOMS, PROBABILITY FUNCTION, PROBABILITY INEQUALITY, STATISTICAL DISTRIBUTION, STATISTICS

Probability Axioms

Given an event E in a SAMPLE SPACE S which is either finite with N elements or countably infinite with $N = \infty$ elements, then we can write

$$S \equiv \left(\bigcup_{i=1}^{N} E_i\right),$$

and a quantity $P(E_i)$, called the PROBABILITY of event E_i, is defined such that

1. $0 \le P(E_i) < 1$.
2. $P(S) = 1$.
3. Additivity: $P(E_1 \cup E_2) = P(E_1) + P(E_2)$, where E_1 and E_2 are mutually exclusive.
4. Countable additivity: $P(\cup_{i=1}^{n} E_i) = \Sigma_{i=1}^{n} P(E_i)$ for $n = 1, 2, \ldots, N$ where $E_1, E_2, \ldots$are mutually exclusive (i.e., $E_1 \cap E_2 = \varnothing$).

Probability Density Function

PROBABILITY FUNCTION

Probability Distribution Function

PROBABILITY FUNCTION

Probability Function

The probability function $P(x)$ (also called the probability density or density function) of a continuous distribution is defined as the derivative of the (cumulative) DISTRIBUTION FUNCTION $D(x)$,

$$D'(x) = [P(x)]_{-\infty}^{x} = P(x) - P(-\infty) = P(x), \tag{1}$$

so

$$D(x) = P(X \le x) \equiv \int_{-\infty}^{x} P(y)\, dy. \tag{2}$$

A probability function satisfies

$$P(x \in B) = \int_B P(x)\, dx \tag{3}$$

and is constrained by the normalization condition,

$$P(-\infty < x < \infty) = \int_{-\infty}^{\infty} P(x)\, dx \equiv 1. \tag{4}$$

Special cases are

$$P(a \le x \le b) = \int_a^b P(x)\, dx \tag{5}$$

$$P(a \le x \le a + da) = \int_a^{a+da} P(x)\, dx \approx P(a)\, da \tag{6}$$

$$P(x = a) = \int_a^a P(x)\, dx = 0. \tag{7}$$

To find the probability function in a set of transformed variables, find the JACOBIAN. For example, If $u = u(x)$, then

$$P_u\,du = P_x\,dx, \tag{8}$$

so

$$P_u = P_x\left|\frac{\partial x}{\partial u}\right|. \tag{9}$$

Similarly, if $u = u(x, y)$ and $v = v(x, y)$, then

$$P_{u,\,v} = P_{x,\,y}\left|\frac{\partial(x,\,y)}{\partial(u,\,v)}\right|. \tag{10}$$

Given the MOMENTS of a distribution (μ, σ, and the GAMMA STATISTICS γ_r), the asymptotic probability function is given by

$$\begin{aligned} P(x) &= Z(x) \\ &-\left[\tfrac{1}{6}\gamma_1 Z^{(3)}(x)\right] + \left[\tfrac{1}{24}\gamma_2 Z^{(4)}(x) + \tfrac{1}{72}\gamma_1^2 Z^{(6)}(x)\right] \\ &-\left[\tfrac{1}{120}\gamma_3 Z^{(5)}(x) + \tfrac{1}{144}\gamma_1\gamma_2 Z^{(7)}(x) + \tfrac{1}{1296}\gamma_1^3 Z^{(9)}(x)\right] \\ &+\left[\tfrac{1}{720}\gamma_4 Z^{(6)}(x) + \left(\tfrac{1}{1152}\gamma_2^2 + \tfrac{1}{720}\gamma_1\gamma_3\right)Z^{(8)}(x)\right. \\ &\left.+\tfrac{1}{1728}\gamma_1^2\gamma_2 Z^{(10)}(x) + \tfrac{1}{31104}\gamma_1^4 Z^{(12)}(x)\right] + \ldots, \end{aligned} \tag{11}$$

where

$$Z(x) = \frac{1}{\sigma\sqrt{2\pi}}\,e^{-(x-\mu)^2/2\sigma^2} \tag{12}$$

is the NORMAL DISTRIBUTION, and

$$\gamma_r = \frac{\kappa_r}{\sigma^{r+2}} \tag{13}$$

for $r \geq 1$ (with κ_r CUMULANTS and σ the STANDARD DEVIATION; Abramowitz and Stegun 1972, p. 935).

Probability Inequality

If $B \supset A$ (B is a SUPERSET of A), then $P(A) \leq P(B)$.

Probability Integral

$$\alpha(x) \equiv \frac{1}{\sqrt{2\pi}}\int_{-x}^{x} e^{-t^2/2}\,dt \tag{1}$$

$$= \sqrt{\frac{2}{\pi}}\int_0^x e^{-t^2/2}\,dt \tag{2}$$

$$= 2\Phi(x) \tag{3}$$

$$= \operatorname{erf}\left(\frac{x}{\sqrt{2}}\right), \tag{4}$$

where $\Phi(x)$ is the NORMAL DISTRIBUTION FUNCTION and ERF is the error function.

See also ERF, NORMAL DISTRIBUTION FUNCTION

Probability Measure

Consider a PROBABILITY SPACE specified by the triple $(S, \mathbb{S}, P)$, where $(S, \mathbb{S})$ is a MEASURABLE SPACE, with S the domain and $\mathbb{S}$ is its measurable subsets, and P is a MEASURE on $\mathbb{S}$ with $P(S) = 1$. Then the MEASURE P is said to be a probability measure. Equivalently, P is said to be normalized.

See also MEASURABLE SPACE, MEASURE, PROBABILITY, PROBABILITY SPACE, RADON MEASURE, STATE SPACE

Probability Space

A triple $(S, \mathbb{S}, P)$ on the domain S, where $(S, \mathbb{S})$ is a MEASURABLE SPACE, $\mathbb{S}$ are the measurable subsets of S, and P is a MEASURE on $\mathbb{S}$ with $P(S) = 1$.

Probable Error

The first quartile of a standard normal distribution occurs when

$$\int_0^t \Phi(z)\,dz = \tfrac{1}{4}.$$

The solution is $t = 0.6745\ldots$. The value of t giving 1/4 is known as the probable error of a normally distributed variate. However, the number δ corresponding to the 50% confidence interval,

$$P(\delta) \equiv 1 - 2\int_0^{|\delta|} \phi(t)\,dt = \tfrac{1}{2},$$

is sometimes also called the probable error.

See also Significance

Probable Prime

A number satisfying Fermat's little theorem (or some other primality test) for some nontrivial base. A probable prime which is shown to be composite is called a pseudoprime (otherwise, of course, it is a prime).

See also Prime Number, Pseudoprime

Problem

A problem is an exercise whose solution is desired. Mathematical "problems" may therefore range from simple puzzles to examination and contest problems to propositions whose proofs require insightful analysis.

There are many unsolved problems in mathematics. Two famous problems which have recently been solved include Fermat's last theorem (by Andrew Wiles) and the Kepler conjecture (by T. C.Hales). Among the most prominent of remaining unsolved problems are the Goldbach conjecture, Riemann hypothesis, Poincaré conjecture, the conjecture that there are an infinite number of twin primes, as well as many more. K.S. Brown, D. Eppstein, S. Finch, and C. Kimberling maintain extensive pages of unsolved problems in mathematics.

See also Unsolved Problems

Procrustian Stretch

HYPERBOLIC ROTATION

Product

The term "product" refers to the result of one or more MULTIPLICATIONS. For example, the mathematical statement $a \times b = c$ would be read "a TIMES b EQUALS c," where c is the product.

The product symbol is defined by

$$\prod_{i=1}^{n} f_i \equiv f_1 \cdot f_2 \cdots f_n.$$

Useful product identities include

$$\ln\left(\prod_{i=1}^{\infty} f_i\right) = \sum_{i=1}^{\infty} \ln f_i$$

$$\prod_{i=1}^{\infty} f_i = \exp\left(\sum_{i=1}^{\infty} \ln f_i\right).$$

For $0 \leq a_i < 1$, then the products $\prod_{i=1}^{\infty}(1+a_i)$ and $\prod_{i=1}^{\infty}(1-a_i)$ converge and diverge as $\prod_{i=1}^{\infty} a_i$.

Projection

A projection is the transformation of POINTS and LINES in one PLANE onto another PLANE by connecting

corresponding points on the two planes with PARALLEL lines. This can be visualized as shining a (point) light source (located at infinity) through a translucent sheet of paper and making an image of whatever is drawn on it on a second sheet of paper. The branch of geometry dealing with the properties and invariants of geometric figures under projection is called PROJECTIVE GEOMETRY.

The projection of a VECTOR **a** onto a VECTOR **u** is given by

$$\text{proj}_{\mathbf{u}}\mathbf{a}=\frac{\mathbf{a}\cdot\mathbf{u}}{|\mathbf{u}|^2}\mathbf{u},$$

where $\mathbf{a}\cdot\mathbf{u}$ is the DOT PRODUCT, and the length of this projection is

$$|\text{proj}_{\mathbf{u}}\mathbf{a}|=\frac{|\mathbf{a}\cdot\mathbf{u}|}{|\mathbf{u}|}.$$

General projections are considered by Foley and VanDam (1983).

The average projected area over all orientations of any ELLIPSOID is 1/4 the total SURFACE AREA. This theorem also holds for any convex solid.

Projection (Vector Space)

If W is a k-dimensional subspace of a vector space V with inner product $\langle,\rangle$, then it is possible to project vectors from V to W. The most familiar projection is when W is the X-AXIS in the plane. In this case, $P(x,\ y)=(x,\ 0)$ is the projection. This projection is an orthogonal projection.

If the SUBSPACE W has an ORTHONORMAL BASIS $\{w_1,\ \ldots,\ w_k\}$ then

$$\text{proj}_W(\mathbf{v})=\sum_{i=1}^{k}\langle\mathbf{v},\ w_i\rangle w_i$$

is the orthogonal projection onto W. Any vector $\mathbf{v}\in V$ can be written uniquely as $\mathbf{v}=\mathbf{v}_W+\mathbf{v}_{W^\perp}$, where $\mathbf{v}_W\in W$ and $\mathbf{v}_{W^\perp}$ is in the ORTHOGONAL SUBSPACE $W^\perp$.

A projection is always a LINEAR TRANSFORMATION and can be represented by a PROJECTION MATRIX. In addition, for any projection, there is an inner product for which it is an orthogonal projection.

See also IDEMPOTENT, INNER PRODUCT, PROJECTION MATRIX, ORTHOGONAL SET, PROJECTION, SYMMETRIC MATRIX, VECTOR SPACE

Projection Matrix

A projection matrix P is an $n\times n$ SQUARE MATRIX that gives a PROJECTION from $\mathbb{R}^n$ to a subspace W. The columns of P are the projections of the standard basis vectors, and W is the image of P. A SQUARE MATRIX P is a projection matrix iff $\mathsf{P}^2=\mathsf{P}$.

The following *Mathematica* function will test if a matrix is a projection matrix.

```
ProjectionMatrixQ[a_List?MatrixQ] := (a.a == a)
```

A projection matrix is a SYMMETRIC MATRIX iff the PROJECTION is orthogonal. In an orthogonal projection, any vector v can be written $v=v_W+v_{W^\perp}$, so

$$\langle v,\ \mathsf{P}w\rangle=\langle v_W,\ \mathsf{P}w\rangle=\langle \mathsf{P}v,\ w\rangle. \qquad (1)$$

An example of a nonsymmetric projection matrix is

$$P = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix}, \quad (2)$$

which projects onto the line $y = x$.

The case of a COMPLEX VECTOR SPACE is analogous. A projection matrix is a HERMITIAN MATRIX iff the PROJECTION satisfies

$$\langle v, \mathsf{P}w \rangle = \langle v_W, \mathsf{P}w \rangle = \langle \mathsf{P}v, w \rangle, \quad (3)$$

where the INNER PRODUCT is the HERMITIAN INNER PRODUCT. Projection operators play a role in quantum mechanics and quantum computing. The following *Mathematica* function gives the Hermitian projection matrix onto a complex subspace, given a basis.

```
< <LinearAlgebra'Orthogonalization';
   HermProjectMatrixOntoBasis[a_List?MatrixQ]
: =
  Module[{a1  =  GramSchmidt[a, InnerProduct -
>  (#1.Conjugate[#2] &) ]},
  Transpose[a1].a1]
 ]
```

Any vector in W is fixed by the projection matrix $\mathsf{P}w = w$ for any w in W. Consequently, a projection matrix P has norm equal to one, unless $\mathsf{P} = 0$,

$$||\mathsf{P}|| = \sup_{|x|=1} |\mathsf{P}x| \le 1. \quad (4)$$

See also IDEMPOTENT, INNER PRODUCT, PROJECTION (VECTOR SPACE), ORTHOGONAL SET, SYMMETRIC MATRIX

Projection Operator

$$\tilde{p} \equiv |\phi_i(x)\rangle\langle\phi_i(t)|$$

$$\tilde{p} \sum_j c_j |\phi_j(t)\rangle = c_i |\phi_i(x)\rangle$$

$$\sum_i |\phi_i(x)\rangle\langle\phi_i(x)| = 1.$$

See also BRA, KET

Projection Theorem

Let H be a HILBERT SPACE and M a closed subspace of H. Corresponding to any vector $x \in H$, there is a unique vector $m_0 \in M$ such that

$$||x - m_0|| \le ||x - m||$$

for all $m \in M$. Furthermore, a necessary and sufficient condition that $m_0 \in M$ be the unique minimizing vector is that $x - m_0$ be orthogonal to M (Luenberger 1997, p. 51).

This theorem can be viewed as a formalization of the result that the closest POINT on a PLANE to a point not on the PLANE can be found by dropping a perpendicular.

Projective Geometry

The branch of GEOMETRY dealing with the properties and invariants of geometric figures under PROJECTION. In older literature, projective geometry is sometimes called "higher geometry," "geometry of position," or "descriptive geometry" (Cremona 1960, pp. v-vi).

The most amazing result arising in projective geometry is the DUALITY PRINCIPLE, which states that a duality exists between theorems such as PASCAL'S THEOREM and BRIANCHON'S THEOREM which allows one to be instantly transformed into the other. More generally, *all* the propositions in projective geometry occur in dual pairs, which have the property that, starting from either proposition of a pair, the other can be immediately inferred by interchanging the parts played by the words "POINT" and "LINE."

The AXIOMS of projective geometry are:

1. If A and B are distinct points on a PLANE, there is at least one LINE containing both A and B.
2. If A and B are distinct points on a PLANE, there is not more than one LINE containing both A and B.
3. Any two LINES in a PLANE have at least one point of the PLANE (which may be the POINT AT INFINITY in common.
4. There is at least one LINE on a PLANE.
5. Every LINE contains at least three points of the PLANE.
6. All the points of the PLANE do not belong to the same LINE

(Veblen and Young 1910–8, Kasner and Newman 1989).

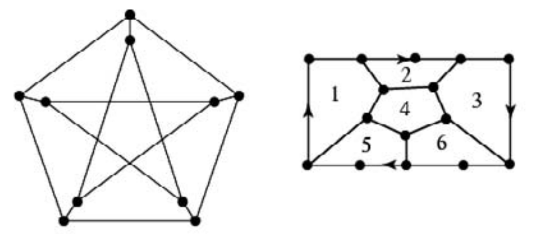
Projective Plane

A projective plane is derived from a usual PLANE by addition of a LINE AT INFINITY. Just as a straight line in projective geometry contains of single POINT AT INFINITY at which the endpoints meet, a plane in projective geometry contains a single LINE AT INFINITY at which the edges of the PLANE meet. A projective plane can be constructed by gluing both pairs of opposite edges of a RECTANGLE together giving both pairs a half-twist. It is a one-sided surface, but cannot be realized in 3-D space without crossing itself.

A finite projective plane of order n is formally defined as a set of n^2+n+1 POINTS with the properties that:

1. Any two POINTS determine a LINE,
2. Any two LINES determine a POINT,
3. Every POINT has $n+1$ LINES on it, and
4. Every LINE contains $n+1$ POINTS.

(Note that some of these properties are redundant.) A projective plane is therefore a SYMMETRIC $(n^2+n+1, n+1, 1)$ BLOCK DESIGN. An AFFINE PLANE of order n exists IFF a projective plane of order n exists.



A finite projective plane exists when the order n is a POWER of a PRIME, i.e., $n=p^a$ for $a \geq 1$. It is conjectured that these are the *only* possible projective planes, but proving this remains one of the most important unsolved problems in COMBINATORICS. The first few orders which *are* powers of primes are 2, 3, 4, 5, 7, 8, 9, 11, 13, 16, ... (Sloane's A000961). The first few orders which are not of this form are 6, 10, 12, 14, 15, ... (Sloane's A024619).

The smallest finite projective plane is of order $n=2$, and consists of the 7_3 CONFIGURATION known as the FANO PLANE. The remarkable BRUCK-RYSER-CHOWLA THEOREM says that if a projective plane of order n exists, and $n = 1$ or 2 (mod 4), then n is the sum of two SQUARES. This rules out $n=6$. By answering LAM'S PROBLEM in the negative using massive computer calculations on top of some mathematics, it has been proved that there are no finite projective planes of order 10 (Lam 1991). The status of the order 12 projective plane remains open.

The projective plane of order 2, also known as the FANO PLANE, is denoted PG(2, 2). It has INCIDENCE MATRIX

$$\begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 & 1 & 0 \end{bmatrix}.$$

Every row and column contains 3 1s, and any pair of rows/columns has a single 1 in common.

Petersen graph *embedding on the projective plane*

The projective plane has EULER CHARACTERISTIC 1, and the HEAWOOD CONJECTURE therefore shows that any set of regions on it can be colored using six colors only (Saaty 1986). The Petersen graph provides a 6-color coloring of the PROJECTIVE PLANE.

Projective Plane Dissection

Virtually nothing is known about dissection of a PROJECTIVE PLANE using unequal squares.

See also CYLINDER DISSECTION, KLEIN BOTTLE DISSECTION, MÖBIUS STRIP DISSECTION, PERFECT SQUARE DISSECTION, TORUS DISSECTION

References

Stewart, I. "Squaring the Square." *Sci. Amer.* **277**, 94–6, July 1997.

Projective Plane PK²

The 2-D SPACE consisting of the set of TRIPLES

$$\{(a,\ b,\ c) : a,\ b,\ c \in K,\ \text{not all zero}\},$$

where triples which are SCALAR multiples of each other are identified.

See also PROJECTIVE PLANE

Projective Space

A SPACE which is invariant under the GROUP G of all general LINEAR homogeneous transformation in the SPACE concerned, but not under all the transformations of any GROUP containing G as a SUBGROUP.

A projective space is the space of 1-D VECTOR SUBSPACES of a given VECTOR SPACE. For REAL VECTOR SPACES, the NOTATION $\mathbb{RP}^n$ or $\mathbb{P}^n$ denotes the REAL projective space of dimension n (i.e., the SPACE of 1-D VECTOR SUBSPACES of $\mathbb{R}^{n+1}$) and $\mathbb{CP}^n$ denotes the COMPLEX projective space of COMPLEX dimension n (i.e., the space of 1-D COMPLEX VECTOR SUBSPACES of $\mathbb{C}^{n+1}$). $\mathbb{P}^n$ can also be viewed as the set consisting of $\mathbb{R}^n$ together with its POINTS AT INFINITY.

See also PROJECTIVE SPACE

Projective Special Linear Group

The projective special linear group $PSL_n(q)$ is the GROUP obtained from the SPECIAL LINEAR GROUP $SL_n(q)$ on factoring by the SCALAR MATRICES contained in that GROUP. It is SIMPLE for $n \geq 2$ except for

$$PSL_2(2) = S_3,$$

$$PSL_3(3) = A_4,$$

and is therefore also denoted $L_n(Q)$.

See also PROJECTIVE SPECIAL ORTHOGONAL GROUP, PROJECTIVE SPECIAL UNITARY GROUP, SPECIAL LINEAR GROUP

References

Conway, J. H.; Curtis, R. T.; Norton, S. P.; Parker, R. A.; and Wilson, R. A. "The Groups $GL_n(q)$, $SL_n(q)$, $PGL_n(q)$, and $PSL_n(q) = L_n(q)$." §2.1 in *Atlas of Finite Groups: Maximal Subgroups and Ordinary Characters for Simple Groups.* Oxford, England: Clarendon Press, p. x, 1985.

Projective Special Orthogonal Group

The projective special orthogonal group $PSO_n(q)$ is the GROUP obtained from the SPECIAL ORTHOGONAL GROUP $SO_n(q)$ on factoring by the SCALAR MATRICES contained in that GROUP. In general, this GROUP is not SIMPLE.

See also PROJECTIVE SPECIAL LINEAR GROUP, PROJECTIVE SPECIAL UNITARY GROUP, SPECIAL ORTHOGONAL GROUP

References

Conway, J. H.; Curtis, R. T.; Norton, S. P.; Parker, R. A.; and Wilson, R. A. "The Groups $GO_n(q)$, $SO_n(q)$, $PGO_n(q)$, and $PSO_n(q)$, and $O_n(q)$." §2.4 in *Atlas of Finite Groups: Maximal Subgroups and Ordinary Characters for Simple Groups.* Oxford, England: Clarendon Press, pp. xi-xii, 1985.

Projective Special Unitary Group

The projective special unitary group $PSU_n(q)$ is the GROUP obtained from the SPECIAL UNITARY GROUP $SU_n(q)$ on factoring by the SCALAR MATRICES contained in that GROUP. $PSU_n(q)$ is SIMPLE except for

$$PSU_2(2) = S_3$$

$$PSU_2(3) = A_4$$

$$PSU_3(2) = 3^2 : Q_8,$$

so it is given the simpler name $U_n(q)$, with $U_2(q) = L_2(q)$.

See also PROJECTIVE SPECIAL LINEAR GROUP, PROJECTIVE SPECIAL ORTHOGONAL GROUP, SPECIAL UNITARY GROUP

References

Conway, J. H.; Curtis, R. T.; Norton, S. P.; Parker, R. A.; and Wilson, R. A. "The Groups $GU_n(q)$, $SU_n(q)$, $PGU_n(q)$, and $PSU_n(q) = U_n(q)$." §2.2 in *Atlas of Finite Groups: Maximal Subgroups and Ordinary Characters for Simple Groups.* Oxford, England: Clarendon Press, p. x, 1985.

Projective Symplectic Group

The projective symplectic group $PSp_n(q)$ is the GROUP obtained from the SYMPLECTIC GROUP $Sp_n(q)$ on factoring by the SCALAR MATRICES contained in that GROUP. $PSp_{2m}(q)$ is SIMPLE except for

$$psp_2(2) = s_3$$

$$psp_2(3) = a_4$$

$$psp_4(2) = s_6,$$

so it is given the simpler name $s_{2m}(q)$, with $s_2(q) = l_2(q)$.

Projective Variety

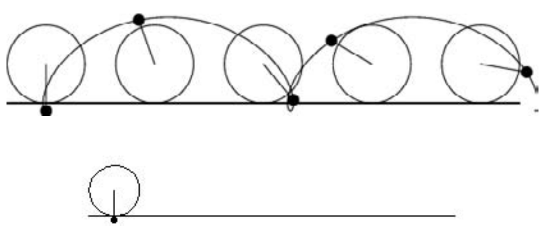
PROJECTIVE ALGEBRAIC VARIETY

Projectivity

The product of any number of PERSPECTIVITIES.

See also INVOLUTION (TRANSFORMATION), PERSPECTIVITY

Projectivization



Given a VECTOR SPACE V, its projectivization $P(V)$, sometimes written $P(V-0)$, is the set of EQUIVALENCE CLASSES $x \sim \lambda x$ for any $\lambda \neq 0$ in $V-0$. For example, COMPLEX PROJECTIVE SPACE has HOMOGENEOUS COORDINATES $[x_0, \ldots, x_n]$, with not all $x_i = 0$.

The projectivization is a MANIFOLD with one less dimension than V. In fact, it is covered by the $n+1$ affine COORDINATE CHARTS,

$$U_0 = \{[1, x_1, \ldots, x_n]\}, \ldots, U_n = \{[x_0, \ldots, x_{n-1}, 1]\}.$$

See also COMPLEX PROJECTIVE SPACE, MANIFOLD, VECTOR SPACE

Prolate Cycloid

The path traced out by a fixed point at a RADIUS $b > a$, where a is the RADIUS of a rolling CIRCLE, also sometimes called an EXTENDED CYCLOID. The prolate cycloid contains loops, and has PARAMETRIC EQUATIONS

$$x = a\phi - b \sin \phi \tag{1}$$

$$y = a - b \cos \phi. \tag{2}$$

The ARC LENGTH from $\phi = 0$ is

$$s = 2(a+b)E(u), \tag{3}$$

where

$$\sin\left(\tfrac{1}{2}\phi\right) = \operatorname{sn} u \tag{4}$$

$$k^2 = \frac{4ab}{(a+c)^2}. \tag{5}$$

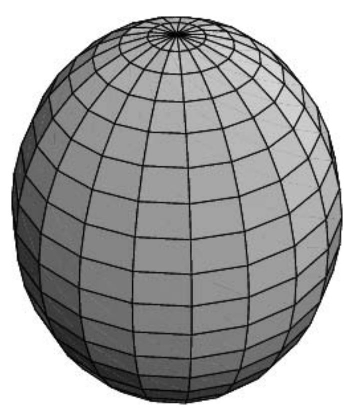
Prolate Cycloid Evolute



The EVOLUTE of the PROLATE CYCLOID is given by

$$x = \frac{a[-2b\phi + 2a\phi \cos \phi - 2a \sin \phi + b \sin(2\phi)]}{2(a \cos \phi - b)}$$

$$y = \frac{a(a - b \cos \phi)^2}{b(a \cos \phi - b)}.$$

Prolate Spheroid

A SPHEROID which is "pointy" instead of "squashed," i.e., one for which the polar radius c is greater than the equatorial radius a, so $c > a$ (called "spindle-shaped ellipsoid" by Tietze 1965, p. 27). A symmetrical egg (i.e., with the same shape at both ends) would approximate a prolate spheroid. A prolate spheroid is a SURFACE OF REVOLUTION obtained by rotating an ELLIPSE about its major axis (Hilbert and Cohn-Vossen 1999, p. 10), and has Cartesian equations

$$\frac{x^2 + y^2}{a^2} + \frac{z^2}{c^2} = 1. \tag{1}$$

The ELLIPTICITY of the prolate spheroid is defined by

$$e \equiv \sqrt{\frac{c^2 - a^2}{c^2}} = \frac{\sqrt{c^2 - a^2}}{c} = \sqrt{1 - \frac{a^2}{c^2}}, \qquad (2)$$

so that

$$1 - e^2 = \frac{a^2}{c^2}. \qquad (3)$$

Then

$$r = a\left(1 + \frac{e^2}{1 - e^2} \sin^2 \delta\right)^{-1/2}. \qquad (4)$$

The SURFACE AREA of a prolate spheroid can be computed as a SURFACE OF REVOLUTION about the z-AXIS,

$$S = 2\pi \int r(z)\sqrt{1 + [r'(z)]^2}\, dz \qquad (5)$$

with radius as a function of z given by

$$r(z) = a\sqrt{1 - \left(\frac{z}{c}\right)^2}. \qquad (6)$$

The INTEGRAND is then

$$r\sqrt{1 + r'^2} = a\sqrt{1 + \frac{(a - c)(a + c)z^2}{c^4}}, \qquad (7)$$

and the integral is given by

$$S = 2\pi a \int_{-c}^{c} \sqrt{1 + \frac{(a - c)(a + c)z^2}{c^4}} dz$$

$$= 2\pi a^2 + \frac{2\pi a c^2}{\sqrt{c^2 - a^2}} \sin^{-1}\left(\frac{\sqrt{c^2 - a^2}}{c}\right). \qquad (8)$$

Using the identity

$$\sqrt{c^2 - a^2} = ce \qquad (9)$$

gives

$$S = 2\pi a^2 + 2\pi \frac{ac}{e} \sin^{-1} e \qquad (10)$$

(Beyer 1987, p. 131). Note that this is the conventional form in which the surface area of an prolate spheroid is written, although it is formally equivalent to the conventional form for the OBLATE SPHEROID via the identity

$$\frac{c^2\pi}{e(a,\, c)} \ln\left[\frac{1 + e(a,\, c)}{1 - e(a,\, c)}\right] = \frac{2\pi ac}{e(c,\, a)} \sin^{-1}[e(c,\, a)], \qquad (11)$$

where $e(x,\, y)$ is defined by

$$e(x,\, y) \equiv \sqrt{1 - \frac{x^2}{y^2}}. \qquad (12)$$

The VOLUME of an prolate spheroid can be computed from the formula for a general ELLIPSOID with $b = a$,

$$V = \tfrac{4}{3} \pi a^2 c \qquad (13)$$

(Beyer 1987, p. 131).

Prolate Spheroidal Coordinates

A system of CURVILINEAR COORDINATES in which two sets of coordinate surfaces are obtained by revolving the curves of the ELLIPTIC CYLINDRICAL COORDINATES about the x-AXIS, which is relabeled the z-AXIS. The third set of coordinates consists of planes passing through this axis.

$$x = a \sinh \xi \sin \eta \cos \phi \qquad (1)$$

$$y = a \sinh \xi \sin \eta \sin \phi \qquad (2)$$

$$z = a \cosh \xi \cos \eta, \qquad (3)$$

where $\xi \in [0,\, \infty)$, $\eta \in [0,\, \pi]$, and $\phi \in [0,\, 2\pi)$. Note that several conventions are in common use; Arfken (1970) uses $(u,\, v,\, \varphi)$ instead of $(\xi,\, \eta,\, \phi)$, and Moon and Spencer (1988, p. 28) use $(\eta,\, \theta,\, \psi)$.
In this coordinate system, the SCALE FACTORS are

$$h_\xi = a\sqrt{\sinh^2 \xi + \sin^2 \eta} \qquad (4)$$

$$h_\eta = a\sqrt{\sinh^2 \xi + \sin^2 \eta} \qquad (5)$$

$$h_\phi = a \sinh \xi \sin \eta. \qquad (6)$$

The LAPLACIAN is

$$\nabla^2 f = \frac{1}{\sin \eta \sinh \xi (\sin^2 \eta + \sinh^2 \xi)} \times \left\{ \frac{\partial}{\partial \xi} \left(\sin \eta \sinh \xi \frac{\partial f}{\partial \xi} \right) + \frac{\partial}{\partial \eta} \left(\sin \eta \sinh \xi \frac{\partial f}{\partial \eta} \right) + \frac{\partial}{\partial \phi} \left[(\operatorname{csch} \xi \sin \eta + \csc \eta \sinh \xi) \frac{\partial f}{\partial \phi} \right] \right\}. \qquad (7)$$

$$= \frac{1}{\sin^2 \eta + \sinh^2 \xi} \left[(\csc^2 \eta + \operatorname{csch}^2 \xi) \frac{\partial^2 f}{\partial \xi^2} + \cot \eta \frac{\partial f}{\partial \eta} + \frac{\partial^2 f}{\partial \eta^2} + \coth \xi \frac{\partial f}{\partial \xi} + \frac{\partial^2 f}{\partial \xi^2} \right] \qquad (8)$$

An alternate form useful for "two-center" problems is defined by

$$\xi_1 = \cosh \xi \qquad (9)$$

$$\xi_2 = \cos \eta \qquad (10)$$

$$\xi_3 = \phi, \qquad (11)$$

where $\xi_1 \in [1, \infty]$, $\xi_2 \in [-1, 1]$, and $\xi_3 \in [0, 2\pi)$ (Abramowitz and Stegun 1972). In these coordinates,

$$z = a \xi_1 \xi_2 \qquad (12)$$

$$x = a \sqrt{(\xi_1^2 - 1)(1 - \xi_2^2)} \cos \xi_3 \qquad (13)$$

$$y = a \sqrt{(\xi_1^2 - 1)(1 - \xi_2^2)} \sin \xi_3. \qquad (14)$$

In terms of the distances from the two FOCI,

$$\xi_1 = \frac{r_1 + r_2}{2a} \qquad (15)$$

$$\xi_2 = \frac{r_1 - r_2}{2a} \qquad (16)$$

$$2a = r_{12}. \qquad (17)$$

The SCALE FACTORS are

$$h_{\xi_1} = a \sqrt{\frac{\xi_1^2 - \xi_2^2}{\xi_1^2 - 1}} \qquad (18)$$

$$h_{\xi_2} = a \sqrt{\frac{\xi_1^2 - \xi_2^2}{1 - \xi_2^2}} \qquad (19)$$

$$h_{\xi_3} = a \sqrt{(\xi_1^2 - 1)(1 - \xi_2^2)}, \qquad (20)$$

and the LAPLACIAN is

$$\nabla^2 f = \frac{1}{a^2} \left\{ \frac{1}{\xi_1^2 - \xi_2^2} \frac{\partial}{\partial \xi_1} \left[(\xi_1^2 - 1) \frac{\partial f}{\partial \xi_1} \right] + \frac{1}{\xi_1^2 - \xi_2^2} \frac{\partial}{\partial \xi_2} \left[(1 - \xi_2^2) \frac{\partial f}{\partial} \right] + \frac{1}{(\xi_1^2 - 1)(1 - \xi_2^2)} \frac{\partial^2 f}{d \xi_2^2} \right\}. \qquad (21)$$

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in prolate spheroidal coordinates.

Prolate Spheroidal Wave Function

The WAVE EQUATION in PROLATE SPHEROIDAL COORDINATES is

$$\nabla^2 \Phi + k^2 \Phi = \frac{\partial}{\partial \xi_1} \left[(\xi_1^2 - 1) \frac{\partial \Phi}{\partial \xi_1} \right] + \frac{\partial}{\partial \xi_2} \left[(1 - \xi_2^2) \frac{\partial \Phi}{\partial \xi_2} \right] + \frac{\xi_1^2 - \xi_2^2}{(\xi_1^2 - 1)(1 - x_2^2)} \frac{\partial^2 \Phi}{\partial \phi^2} + c^2 (\xi_1^2 - \xi_2^2) \Phi = 0, \qquad (1)$$

where

$$c \equiv \tfrac{1}{2} ak. \qquad (2)$$

Substitute in a trial solution

$$\Phi = R_{mn}(c, \xi_1) S_{mn}(c, \xi_2) \begin{matrix} \cos \\ \sin \end{matrix} (m\phi) \qquad (3)$$

$$\frac{d}{d\xi_1} \left[(\xi_1^2 - 1) \frac{d}{d\xi_1} R_{mn}(c, \xi_1) \right]$$

$$-\left(\lambda_{mn}-c^2\xi_1^2+\frac{m^2}{\xi_1^2-1}\right)R_{mn}(c,\ \xi_1)=0. \quad (4)$$

The radial differential equation is

$$\frac{d}{d\xi_2}\left[(\xi_2^2-1)\frac{d}{d\xi_2}S_{mn}(c,\ \xi_2)\right] -\left(\lambda_{mn}-c^2\xi_2^2+\frac{m^2}{\xi_2^2-1}\right)R_{mn}(c,\ \xi_2)=0. \quad (5)$$

and the angular differential equation is

$$\frac{d}{d\xi_2}\left[(1-\xi_2^2)\frac{d}{d\xi_2}S_{mn}(c,\ \xi_2)\right] -\left(\lambda_{mn}-c^2\xi_2^2+\frac{m^2}{1-\xi_2^2}\right)R_{mn}(c,\ \xi_2)=0. \quad (6)$$

Note that these are identical (except for a sign change). The prolate angular function of the first kind is given by

$$S_{mn}^{(1)}=\begin{cases}\sum_{r=1,\ 3,\ \ldots}^{\infty} d_r(c)P_{m+r}^m(\eta) & \text{for } n-m \text{ odd}\\ \sum_{r=0,\ 2,\ \ldots}^{\infty} d_r(c)P_{m+r}^m(\eta) & \text{for } n-m \text{ even,}\end{cases} \quad (7)$$

where $P_k^k(\eta)$ is an associated LEGENDRE POLYNOMIAL. The prolate angular function of the second kind is given by

$$S_{mn}^{(2)}=\begin{cases}\sum_{r=\ldots,\ -1,\ 1,\ 3,\ \ldots}^{\infty} d_r(c)Q_{m+r}^m(\eta) & \text{for } n-m \text{ odd}\\ \sum_{r=\ldots,\ -2,\ 0,\ 2,\ \ldots}^{\infty} d_r(c)Q_{m+r}^m(\eta) & \text{for } n-m \text{ even,}\end{cases} \quad (8)$$

where $Q_k^m(\eta)$ is an associated LEGENDRE FUNCTION OF THE SECOND KIND and the COEFFICIENTS d_r satisfy the RECURRENCE RELATION

$$\alpha_k d_{k+2}+(\beta_k-\lambda_{mn})d_k+\gamma_k d_{k-2}=0, \quad (9)$$

with

$$\alpha_k=\frac{(2m+k+2)(2m+k+1)c^2}{(2m+2k+3)(2m+2k+3)} \quad (10)$$

$$\beta_k=(m+k)(m+k+1) +\frac{2(m+k)(m+k+1)-2m^2-1}{(2m+2k-1)(2m+2k+3)}c^2 \quad (11)$$

$$\gamma_k=\frac{k(k-1)c^2}{(2m+2k-3)(2m+2k-1)}. \quad (12)$$

Various normalization schemes are used for the ds (Abramowitz and Stegun 1972, p. 758). Meixner and Schäfke (1954) use

$$\int_{-1}^{1}[S_{mn}(c,\ \eta)]^2\,d\eta=\frac{2}{2n+1}\frac{(n+m)!}{(n-m)!}. \quad (13)$$

Stratton *et al.* (1956) use

$$\frac{(n+m)!}{(n-m)!}=\begin{cases}\sum_{r=1,\ 3,\ \ldots}^{\infty}\frac{(r+2m)!}{r!}d_r & \text{for } n-m \text{ odd}\\ \sum_{r=0,\ 2,\ \ldots}^{\infty}\frac{(r+2m)!}{r!}d_r & \text{for } n-m \text{ even.}\end{cases} \quad (14)$$

Flammer (1957) uses

$$S_{mn}(c,\ 0)=\begin{cases}P_n^{m+1}(0) & \text{for } n-m \text{ odd}\\ P_n^m(0) & \text{for } n-m \text{ even.}\end{cases} \quad (15)$$

Pronic Number

A FIGURATE NUMBER OF THE FORM $P_n=2T_n=n(n+1)$, where T_n is the nth TRIANGULAR NUMBER. The first few are 2, 6, 12, 20, 30, 42, 56, 72, 90, 110, ... (Sloane's A002378). The GENERATING FUNCTION of the pronic numbers is

$$\frac{2x}{(1-x)^3}=2x+6x^2+12x^3+20x^4+\ldots$$

Kausler (1805) was one of the first to tabulate pronic numbers, creating a list up to $n=1000$ (Dickson 1952, Vol. 1, p. 357; Vol. 2, p. 233). Pronic numbers are also known as oblong or heteromecic numbers.

McDaniel (1998ab) proved that the only pronic Fibonacci numbers are $F_0=0$ and $F_3=2$, and the only pronic Lucas number is $L_0=2$, rediscovering a result first published by Ming (1995).

The first few n for which P_n are PALINDROMIC are 1, 2, 16, 77, 538, 1621, ... (Sloane's A028336), and the first few PALINDROMIC NUMBERS which are pronic are 2, 6, 272, 6006, 289982, ... (Sloane's A028337).

Proof

A rigorous mathematical argument which unequivocally demonstrates the truth of a given PROPOSITION. A mathematical statement which has been proven is called a THEOREM.

According to Hardy (1999, pp. 15–6), "all physicists, and a good many quite respectable mathematicians, are contemptuous about proof. I have heard Professor Eddington, for example, maintain that proof, as pure mathematicians understand it, is really quite uninteresting and unimportant, and that no one who is really certain that he has found something good should waste his time looking for proof.... [This opinion], with which I am sure that almost all physicists agree at the bottom of their hearts, is one to which a mathematician ought to have some reply."

There is some debate among mathematicians as to just what constitutes a proof. The FOUR-COLOR THEOREM is an example of this debate, since its "proof" relies on an exhaustive computer testing of many individual cases which cannot be verified "by hand." While many mathematicians regard computer-assisted proofs as valid, some purists do not. There are several computer systems currently under development for automated theorem proving, among them, *THƎOREM∀*.

Proofreading Mistakes

If proofreader A finds a mistakes and proofreader B finds b mistakes, c of which were also found by A, how many mistakes were missed by both A and B? Assume there are a total of m mistakes, so proofreader A finds a FRACTION a/m of all mistakes, and also a FRACTION c/b of the mistakes found by B. Assuming these fractions are the same, then solving for m gives

$$m = \frac{ab}{c}.$$

The number of mistakes missed by both is therefore approximately

$$N = m - a - b + c = \frac{(a-c)(b-c)}{c}.$$

Proper Class

A CLASS which is not a SET.

See also CLASS (SET), ORDINAL NUMBER, SET

Proper Cover

Proper covers are defined as COVERS of a set X which do not contain the entire set X itself as a subset (Macula 1994). Of the five covers of $\{1, 2\}$, namely $\{\{1\}, \{2\}\}$, $\{\{1, 2\}\}$, $\{\{1\}, \{1, 2\}\}$, $\{\{2\}, \{1, 2\}\}$, and $\{\{1\}, \{2\}, \{1, 2\}\}$, only $\{\{1\}, \{2\}\}$ does not contain the subset $\{1, 2\}$ and so is the unique proper cover of two elements. In general, the number of proper covers for a set of N elements is

$$|C'(N)| = |C(N)| - \tfrac{1}{4}\,2^{2^N}$$

$$= \left[\frac{1}{2}\sum_{k=0}^{N}(-1)^k\binom{N}{k}2^{2^{N-k}}\right] - \frac{2^{2^N}}{4},$$

the first few of which are 0, 1, 45, 15913, 1073579193, ... (Sloane's A007537).

See also COVER, MINIMAL COVER

Proper Divisor

A positive proper divisor is a positive DIVISOR of a number n, excluding n itself. For example, 1, 2, and 3 are positive proper divisors of 6, but 6 itself is not. The number of proper divisors of n is therefore given by

$$s_0(n) \equiv \sigma_0(n) - 1,$$

where $\sigma_k(n)$ is the DIVISOR FUNCTION. For $n = 1, 2, ...,$ $s_0(n)$ is therefore given by 0, 1, 1, 2, 1, 3, 1, 3, 2, 3, ... (Sloane's A032741). The largest proper divisors of $n = 2, 3, ...$ are 1, 1, 2, 1, 3, 1, 4, 3, 5, 1, ... (Sloane's A032742).

The term "proper divisor" is sometimes includes negative integer divisors of a number n excluding $-n$. Using this definition, -3, -2, -1, 1, 2, and 3 are the proper divisors of 6, while –6 and 6 are the IMPROPER DIVISORS.

To make matters even more confusing, the proper divisor is often defined so that -1 and 1 are also excluded. Using this alternative definition, the proper divisors of 6 would then be -3, -2, 2, and 3, and the IMPROPER DIVISORS would be –6, -1, 1, and 6.

Proper Fraction

A FRACTION $p/q < 1$. A fraction $p/q > 1$ is called an IMPROPER FRACTION.

See also FRACTION, MIXED FRACTION, IMPROPER FRACTION, REDUCED FRACTION

Proper Integral

An INTEGRAL which has neither limit INFINITE and from which the INTEGRAND does not approach INFINITY at any point in the range of integration.

See also IMPROPER INTEGRAL, INTEGRAL

Proper k-Coloring

k-COLORING

Proper Subfield

See also FIELD, SUBFIELD

Proper Subset

A SUBSET which is not the entire SET. For example, consider a SET $\{1, 2, 3, 4, 5\}$. Then $\{1, 2, 4\}$ and $\{1\}$ are proper subsets, while $\{1, 2, 6\}$ and $\{1, 2, 3, 4, 5\}$ are not.

See also SET, SUBSET

Proper Superset

A SUPERSET which is not the entire SET.

Proper Value

EIGENVALUE

Proper Vector

EIGENVECTOR

Property P

A KNOT having the property that no surgery could possibly yield a counterexample to the POINCARÉ CONJECTURE is said to satisfy Property P (Adams 1994, p. 262).

See also POINCARÉ CONJECTURE

References

Adams, C. C. *The Knot Book: An Elementary Introduction to the Mathematical Theory of Knots.* New York: W. H. Freeman, 1994.

Proportional

If a is (directly) proportional to b, then a/b is a constant. The relationship is written $a \propto b$, which implies

$$a = cb,$$

for some constant c.

See also DIRECTLY PROPORTIONAL, INVERSELY PROPORTIONAL

Proportional-Integral-Derivative Method

A very useful active feedback method for controlling things like temperature control systems, servo motors, and flow control valves.

Proposition

A statement which is to be proved.

Propositional Calculus

The formal basis of LOGIC dealing with the notion and usage of words such as "NOT," "OR," "AND," and "IMPLIES." Many systems of propositional calculus have been devised which attempt to achieve consistency, completeness, and independence of AXIOMS. The term "sentential calculus" is sometimes used as a synonym for propositional calculus.

See also CONNECTIVE, LOGIC, P-SYMBOL, PREDICATE CALCULUS

Propositional Connective

CONNECTIVE

Prosthaphaeresis Formulas

TRIGONOMETRY formulas which convert a product of functions into a sum or difference. The Prosthaphaeresis formulas are

$$\sin\alpha + \sin\beta = 2\sin\left[\tfrac{1}{2}(\alpha+\beta)\right]\cos\left[\tfrac{1}{2}(\alpha-\beta)\right] \quad (1)$$

$$\sin\alpha - \sin\beta = 2\cos\left[\tfrac{1}{2}(\alpha+\beta)\right]\sin\left[\tfrac{1}{2}(\alpha-\beta)\right] \quad (2)$$

$$\cos\alpha + \cos\beta = 2\cos\left[\tfrac{1}{2}(\alpha+\beta)\right]\cos\left[\tfrac{1}{2}(\alpha-\beta)\right] \quad (3)$$

$$\cos\alpha - \cos\beta = -2\sin\left[\tfrac{1}{2}(\alpha+\beta)\right]\sin\left[\tfrac{1}{2}(\alpha-\beta)\right]. \quad (4)$$

Related formulas are

$$\sin\alpha\sin\beta = \tfrac{1}{2}[\sin(\alpha-\beta)+\sin(\alpha+\beta)] \quad (5)$$

$$\cos\alpha\cos\beta = \tfrac{1}{2}[\cos(\alpha-\beta)+\cos(\alpha+\beta)] \quad (6)$$

$$\cos\alpha\sin\beta = \tfrac{1}{2}[\sin(\alpha+\beta)-\sin(\alpha-\beta)] \quad (7)$$

$$\sin\alpha\sin\beta = \tfrac{1}{2}[\cos(\alpha-\beta)-\cos(\alpha+\beta)]. \quad (8)$$

Multiplying both sides by 2 gives the equations sometimes known as the WERNER FORMULAS.

See also TRIGONOMETRIC ADDITION FORMULAS, TRIGONOMETRIC PRODUCT FORMULAS

Proth's Theorem

For $N = h \cdot 2^n + 1$ with ODD h and $2^n > h$, if there exists an INTEGER a such that

$$a^{(N-1)/2} \equiv -1 \pmod N,$$

then N is PRIME.

Protractor

A ruled SEMICIRCLE used for measuring and drawing ANGLES.

Prouhet's Problem

PROUHET-TARRY-ESCOTT PROBLEM

Prouhet-Tarry-Escott Problem

Find two *distinct* sets of integers $\{a_1, \ldots, a_n\}$ and $\{b_1, \ldots, b_n\}$, such that for $k = 1, \ldots, m$,

$$\sum_{i=1}^{n} a_i^k = \sum_{i=1}^{n} b_i^k.$$

The Prouhet-Tarry-Escott problem is therefore a special case of a MULTIGRADE EQUATION. A solution with $n = m + 1$ is said to be "ideal," and are of interest because they are minimal solutions of the problem (Borwein and Ingalls 1994).

The smallest symmetric ideal solutions for $m = 9$ was found by Borwein *et al.* (Lisonek 2000),

$$\begin{aligned}(-313)^k &+ (-301)^k + (-188)^k + (-100)^k + (-99)^k \\ &+99^k + 100^k + 188^k + 301^k + 313^k \\ &= (-308)^k + (-307)^k + (-180)^k + (-131)^k + (-71)^k \\ &+71^k + 131^k + 180^k + 307^k + 308^k, \end{aligned} \quad (1)$$

as well as the second solution

$$(-515)^k + (-452)^k + (-366)^k + (-189)^k + (-103)^k$$
$$+103^k + 189^k + 366^k + 452^k + 515^k$$

$$= (-508)^k + (-417)^k + (-331)^k + (-245)^k + (-18)^k$$

$$+18^k + 245^k + 331^k + 471^k + 508^k. \qquad (2)$$

The previous smallest known symmetric ideal solution, found by Letac in the 1940s, is

$$(-23750)^k + (-20667)^k + (-20499)^k + (-11857)^k$$

$$+(-436)^k + 436^k + 11857^k + 20449^k + 20667^k + 23750^k$$

$$= (-23738)^k + (-20855)^k + (-20231)^k + (-11881)^k$$

$$+(-12)^k + 12^k + 11881^k + 20231^k + 20885^k + 23738^k. \qquad (3)$$

In 1999, S. Chen found the first ideal solution with $m \geq 10$,

$$0^k + 11^k + 24^k + 65^k + 90^k + 129^k + 173^k + 212^k$$

$$+237^k + 278^k + 291^k + 302^k$$

$$= 3^k + 5^k + 30^k + 57^k + 104^k + 116^k + 186^k$$

$$+198^k + 245^k + 272^k + 297^k + 299^k, \qquad (4)$$

which is true for $k = 1, 2, ..., 11$.

Prüfer Code

An encoding which provides a bijection between the n^{n-2} labeled trees on n nodes and strings of $n-2$ integers chosen from an alphabet of the numbers 1 to n. A labeled tree can be converted to a Prüfer code using `LabeledTreeToCode[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`), and a code can be converted to a labeled tree using `CodeToLabeledTree[g]`.

Prüfer's bijection is based on the fact that every tree has at least two nodes of degree 1 (i.e., leaves). Therefore, the node v which is incident to the lowest labeled leaf is uniquely determined, and v is then taken as the first symbol in the code. This node is then deleted and the procedure is repeated until a single edge is left, giving a total of $n-2$ integers between 1 and n (Skiena 1990). This is demonstrated in the labeled tree shown above.

Pseudoconic Projection

A MAP PROJECTION in which the parallels are represented by concentric circular arcs and the meridians by concurrent curves.

References

Lee, L. P. "The Nomenclature and Classification of Map Projections." *Empire Survey Rev.* **7**, 190–00, 1944.

Pseudocrosscap

A surface constructed by placing a family of figure-eight curves into $\mathbb{R}^3$ such that the first and last curves reduce to points. The surface has PARAMETRIC EQUATIONS

$$x(u, v) = (1 - u^2) \sin v$$

$$y(u, v) = (1 - u^2) \sin(2v)$$

$$z(u, v) = u.$$

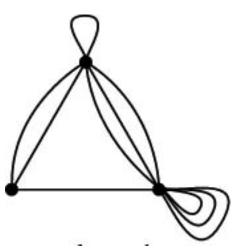
Pseudo-Euclidean Space

A Euclidean-like space having LINE ELEMENT

$$ds^2 = (dz^1)^2 + \ldots + (dz^p)^2 - (dz^{p+1})^2 - \ldots - (dz^{p+q})^2,$$



having dimension $m = p + q$ (Rosen 1965). In contrast, the signs would be all be positive for a EUCLIDEAN SPACE.

Pseudoparadox

Curry (1977, p. 5) uses the term pseudoparadox to describe an apparent PARADOX, such as the CATALOGUE PARADOX, for which there is no underlying actual contradiction.

See also HYPERGAME, PARADOX

References

Curry, H. B. *Foundations of Mathematical Logic.* New York: Dover, p. 5, 1977.

Pseudoperfect Number

SEMIPERFECT NUMBER

Pseudoprime

A pseudoprime is a COMPOSITE NUMBER which passes a test or sequence of tests which fail for most COMPOSITE NUMBERS. Unfortunately, some authors drop the "COMPOSITE" requirement, calling any number which passes the specified tests a pseudoprime even if it is PRIME. Pomerance, Selfridge, and Wagstaff (1980) restrict their use of "pseudoprime" to ODD COMPOSITE NUMBERS. "Pseudoprime" used without qualification means FERMAT PSEUDOPRIME.

CARMICHAEL NUMBERS are ODD COMPOSITE numbers which are pseudoprimes to every base; they are sometimes called ABSOLUTE PSEUDOPRIMES. The following table gives the number of FERMAT PSEUDOPRIMES psp(2), EULER-JACOBI PSEUDOPRIMES ejpsp(2), and STRONG PSEUDOPRIMES spsp(2) to the base 2, as well as CARMICHAEL NUMBERS CN which are less the first few powers of 10 (Guy 1994).

10^n	psp(2)	ejpsp(2)	spsp(2)	CN
Sloane	A055550	A055551	A055552	A055553
Sloane Counts	A001567	A047713	A001262	A002997
10^1	0	0	0	0
10^2	0	0	0	0
10^3	3	1	0	1
10^4	22	12	5	7

Pseudorhombicuboctahedron

Elongated Square Gyrobicupola

Pseudo-Riemannian Manifold

A pseudo-Riemannian manifold is a manifold which has a metric that is of the signature diag$(-, +, \ldots, +)$, as compared to a Riemannian manifold, which has a signature of all positive signs.

See also Campbell's Theorem, Riemannian Manifold

Pseudoscalar

A scalar which reverses sign under inversion is called a pseudoscalar. The scalar triple product

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C})$$

is a pseudoscalar. Given a transformation matrix A,

$$S' = \det|\mathsf{A}|S,$$

where det is the determinant.

See also Pseudotensor, Pseudovector, Scalar

Pseudosmarandache Function

The pseudosmarandache function $Z(n)$ is the smallest integer such that

$$\sum_{k=1}^{Z(n)} k = \tfrac{1}{2} Z(n)[Z(n)+1]$$

is divisible by n. The values for $n = 1, 2, \ldots$ are 1, 3, 2, 7, 4, 3, 6, 15, 8, 4, ... (Sloane's A011772; Kashihara 1996; Russo 2000, p. 4).

Pseudosphere

Half the SURFACE OF REVOLUTION generated by a TRACTRIX about its ASYMPTOTE to form a TRACTROID. The surfaces is sometimes also called the ANTISPHERE or TRACTRISOID (Steinhaus 1983, pp. 251). The Cartesian PARAMETRIC EQUATIONS are

$$x = \operatorname{sech} u \cos v \tag{1}$$

$$y = \operatorname{sech} u \sin v \tag{2}$$

$$z = u - \tanh u \tag{3}$$

for $u \geq 0$ and $v \in [0, 2\pi)$.

The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = \tanh^2 u \tag{4}$$

$$F = 0 \tag{5}$$

$$G = \operatorname{sech}^2 u, \tag{6}$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = -\operatorname{sech} u \tanh u \tag{7}$$

$$f = 0 \tag{8}$$

$$g = \operatorname{sech} u \tanh u, \tag{9}$$

and the surface area element is

$$dS = \operatorname{sech} u \tanh u. \tag{10}$$

The SURFACE AREA is

$$S = \int_0^{2\pi} \int_0^{\infty} \operatorname{sech} u \tanh u \, du \, dv = 2\pi. \tag{11}$$

The GAUSSIAN and MEAN CURVATURES are

$$K = -1 \tag{12}$$

$$H = \tfrac{1}{2}(\sinh u - \operatorname{csch} u). \tag{13}$$

The pseudosphere therefore has constant NEGATIVE GAUSSIAN CURVATURE, justifying the name "pseudosphere" (i.e., an analog of the SPHERE, which has constant POSITIVE curvature). Its constant NEGATIVE CURVATURE also makes it a model of HYPERBOLIC GEOMETRY. An equation for the GEODESICS on a pseudosphere is given by

$$\cosh^2 u + (v + c)^2 = k^2. \tag{14}$$

Pseudosquare

Given an ODD PRIME p, a SQUARE NUMBER n satisfies $(n/p) = 0$ or 1 for all $p < n$, where (n/p) is the LEGENDRE SYMBOL. A number $n > 2$ which satisfies this relationship but is not a SQUARE NUMBER is called a pseudosquare. The only pseudosquares less than 10^9 are 3 and 6.

See also LEGENDRE SYMBOL, SQUARE NUMBER

Pseudotensor

A TENSOR-like object which reverses sign under inversion. Given a transformation MATRIX A,

$$A'_{ij} = \det|\mathsf{A}| a_{ik} a_{jl} A_{kl},$$

where det is the DETERMINANT. A pseudotensor is sometimes also called a TENSOR DENSITY.

See also PSEUDOSCALAR, PSEUDOVECTOR, SCALAR, TENSOR DENSITY

References

Arfken, G. "Pseudotensors, Dual Tensors." §3.4 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 128–37, 1985.

Pseudovector

A typical VECTOR is transformed to its NEGATIVE under inversion. A VECTOR which is invariant under inversion is called a pseudovector, also called an AXIAL VECTOR in older literature (Morse and Feshbach 1953). The CROSS PRODUCT

$$\mathbf{A} \times \mathbf{B} \quad (1)$$

is a pseudovector, whereas the VECTOR TRIPLE PRODUCT

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) \quad (2)$$

is a VECTOR.

$$[\text{pseudovector}] \times [\text{pseudovector}] = [\text{pseudovector}] \quad (3)$$

$$[\text{vector}] \times [\text{pseudovector}] = [\text{vector}]. \quad (4)$$

Given a transformation MATRIX A,

$$C_i' = \det|\mathsf{A}| a_{ij} C_j. \quad (5)$$

p-Signature

Diagonalize a form over the rationals to

$$\text{diag}[p^a \cdot A,\ p^b \cdot B,\ \ldots],$$

where all the entries are INTEGERS and A, B, ...are RELATIVELY PRIME to p. Then the p-signature OF THE FORM (for $p \neq -1,\ 2$) is

$$p^a + p^b + \ldots + 4k \pmod 8,$$

where k is the number of ANTISQUARES. For $p = -1$, the p-signature is SYLVESTER'S SIGNATURE.

See also SIGNATURE (QUADRATIC FORM)

PSLQ Algorithm

An algorithm which can be used to find INTEGER RELATIONS between real numbers x_1, ..., x_n such that

$$a_1 x_1 + a_2 x_2 + \ldots + a_n x_n = 0,$$

with not all $a_i = 0$. Although the algorithm operates by manipulating a lattice, it does not reduce it to a short vector basis, and is therefore *not* a LATTICE REDUCTION algorithm. PSLQ is based on a partial sum of squares scheme (like the PSOS ALGORITHM) implemented using QR DECOMPOSITION. It was developed by Ferguson and Bailey (1992). A much simplified version of the algorithm was subsequently developed by Ferguson *et al.* (1999), which also extends the algorithm to complex numbers and quaternions. Ferguson *et al.* (1999) also demonstrated that PSLQ is distinct from the HJLS ALGORITHM.

The PSLQ algorithm terminates after a number of iterations bounded by a polynomial in n and uses a numerically stable matrix reduction procedure (Ferguson and Bailey 1992). PSLQ tends to be faster than the FERGUSON-FORCADE ALGORITHM and LLL ALGORITHM because of clever techniques that allow machine arithmetic to be used at many intermediate steps. The LLL ALGORITHM, by comparison, must use moderate precision, although generally not as much as the HJLS ALGORITHM.

While the LLL ALGORITHM is a more general LATTICE REDUCTION algorithm than PSLQ, using LLL to obtain integer relations is in some sense a "trick," whereas with PSLQ one gets either a relation or lower bounds on degrees of polynomials and sizes of coefficients for which such a relation must satisfy.

Ptolemy Inequality

For a QUADRILATERAL which is not CYCLIC, PTOLEMY'S THEOREM becomes an INEQUALITY:

$$AB \times CD + BC \times DA > AC \times BD.$$

See also PTOLEMY'S THEOREM, QUADRILATERAL

Ptolemy's Theorem

For a CYCLIC QUADRILATERAL, the sum of the products of the two pairs of opposite sides equals the product of the diagonals

$$AB \times CD + BC \times DA = AC \times BD.$$

This fact can be used to derive the TRIGONOMETRY addition formulas.

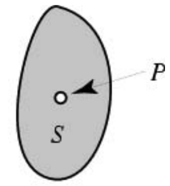
Pullback Map

A pullback is a general CATEGORICAL operation appearing in a number of mathematical contexts, sometimes going under a different name. If $T : V \to W$ is a linear transformation between VECTOR SPACES, then $T^* : W^* \to V^*$ (usually called TRANSPOSE MAP or DUAL MAP because its associated matrix is the MATRIX TRANSPOSE of T) is an example of a pullback map.



In the case of a DIFFEOMORPHISM and DIFFERENTIABLE MANIFOLD, a very explicit definition can be formulated. Given an r-form α on a MANIFOLD M_2, define the r-form $T^*(\alpha)$ on M_1 by its action on an r-tuple of tangent vectors $(X_1, \dots, X_r)$ as the number $T^*(\alpha)(X_1, \dots, X_r) = \alpha(TX_1, \dots, TX_r)$. This defines a map on r-forms and is the pullback map.

Purser's Theorem

Let t, u, and v be the lengths of the tangents to a CIRCLE C from the vertices of a TRIANGLE with sides of lengths a, b, and c. Then the condition that C is tangent to the CIRCUMCIRCLE of the TRIANGLE is that

$$\pm at \pm bu \pm cv = 0.$$

The theorem was discovered by Casey prior to Purser's independent discovery.

See also CASEY'S THEOREM, CIRCUMCIRCLE

Pursuit Curve

If A moves along a known curve, then P describes a pursuit curve if P is always directed toward A and A and P move with uniform velocities. Pursuit curves were considered in general by the French scientist Pierre Bouguer in 1732, and subsequently by the English mathematician Boole. The case restricting A to a straight line was studied by Arthur Bernhart

(MacTutor Archive). It has CARTESIAN COORDINATES equation

$$y = cx - \ln x.$$

The problem of n mice (or dogs) starting at the corners of a regular polygon and running towards each other is called the MICE PROBLEM.

P-Value

The PROBABILITY that a variate would assume a value greater than or equal to the observed value strictly by chance: $P(z \geq z_{\text{observed}})$.

See also ALPHA VALUE, SIGNIFICANCE

Pyramid

A POLYHEDRON with one face (known as the "base") a POLYGON and all the other faces TRIANGLES meeting at a common VERTEX (known as the "apex"). A right pyramid is a pyramid for which the line joining the centroid of the base and the apex is perpendicular to the base. A regular pyramid is a pyramid whose bases is a REGULAR POLYGON. An n-gonal regular pyramid (denoted Y_n) having EQUILATERAL TRIANGLES as sides is possible only for $n = 3, 4, 5$. These correspond to the TETRAHEDRON, SQUARE PYRAMID, and PENTAGONAL PYRAMID, respectively.

An arbitrary pyramid has a single cross-sectional shape whose lengths scale linearly with height. Therefore, the AREA of a CROSS SECTION scales quadratically with height, decreasing from A_b at the base ($z = 0$) to 0 at the apex (assumed to lie at a height $z = h$). The AREA at a height z above the base is therefore given by

$$A(z) = A_b \frac{(h-z)^2}{h^2}. \tag{1}$$

As a result, the VOLUME of a pyramid, regardless of base shape or position of the apex relative to the base, is given by

$$V = \int_0^h A(z)\, dz = A_b \int_0^h \frac{(z-h)^2}{h^2}\, dz = \tfrac{1}{3} A_b h. \tag{2}$$

These results also hold for the CONE, ELLIPTIC CONE, TRIANGULAR PYRAMID, SQUARE PYRAMID, etc.

The CENTROID is the same as for the CONE, given by

$$\bar{z} = \tfrac{1}{4} h. \tag{3}$$

The SURFACE AREA of a pyramid is

$$S = \tfrac{1}{2} ps, \tag{4}$$

where s is the SLANT HEIGHT and p is the base PERIMETER. For a right pyramid with a regular n-gonal base of side length a,

$$s_n = \sqrt{h^2 + R^2} = \sqrt{h^2 + \tfrac{1}{4} a^2 \csc^2\left(\frac{\pi}{n}\right)}. \tag{5}$$

This gives the special cases

$$s_3 = \sqrt{h^2 + \tfrac{1}{3} a^2} \tag{6}$$

$$s_4 = \sqrt{h^2 + \tfrac{1}{2} a^2} \tag{7}$$

$$s_5 = \sqrt{h^2 + \tfrac{1}{10}\left(5 + \sqrt{5}\right) a^2} \tag{8}$$

$$s_6 = \sqrt{h^2 + a^2}. \tag{9}$$

Joining two PYRAMIDS together at their bases gives a BIPYRAMID, also called a DIPYRAMID.

See also BIPYRAMID, CUMULATION, ELEVATUM, ELONGATED PYRAMID, GYROELONGATED PYRAMID, HEXAGONAL PYRAMID, INVAGINATUM, PENTAGONAL PYRAMID, PYRAMID, PYRAMIDAL FRUSTUM, SQUARE PYRAMID, TETRAHEDRON, TRIANGULAR PYRAMID, TRUNCATED SQUARE PYRAMID

Pyramidal Frustum

A pyramidal frustum is a FRUSTUM made by chopping the top off a PYRAMID. It is a special case of a PRISMATOID. Let s be the SLANT HEIGHT, p_1 the bottom base PERIMETER, p_2 the top base PERIMETER, A_1 the bottom AREA, and A_2 the top AREA. Then the SURFACE AREA (of the sides) and VOLUME of a pyramidal frustum are given by

$$S = \tfrac{1}{2}(p_1 + p_2)s \tag{1}$$

$$V = \tfrac{1}{3} h\left(A_1 + A_2 + \sqrt{A_1 A_2}\right). \tag{2}$$

The CENTROID of a right pyramidal frustum occurs at a height

$$\bar{z} = \frac{h\left(A_1 + 2\sqrt{A_1 A_2} + 3A_2\right)}{4\left(A_1 + \sqrt{A_1 A_2} + A_2\right)} \tag{3}$$

above the bottom base (Harris and Stocker 1998).

The bases of a right n-gonal frustum are regular polygons of side lengths a and b with circumradii

$$R_n = \tfrac{1}{2} c \csc\left(\frac{\pi}{n}\right), \tag{4}$$

where c is the side length, so the diagonal connecting corresponding vertices on top and bottom has length

$$x_n = \tfrac{1}{2}(a - b) \csc\left(\frac{\pi}{n}\right), \tag{5}$$

and the SLANT HEIGHT is

$$s_n = \sqrt{d^2 + h^2} = \sqrt{\tfrac{1}{4} \csc\left(\frac{\pi}{n}\right)(a - b)^2 + h^2}. \tag{6}$$

The triangular ($n = 3$) and square ($n = 4$) right pyramidal frustums therefore have side surface areas

$$S_3 = \tfrac{3}{2}(a + b)\sqrt{\tfrac{1}{3}(a - b)^2 + h^2} \tag{7}$$

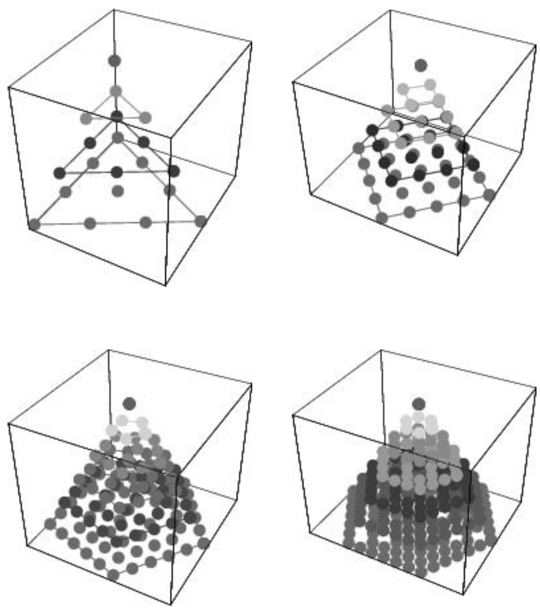
$$S_4 = 2(a + b)\sqrt{\tfrac{1}{2}(a - b)^2 + h^2}. \tag{8}$$

The area of a regular n-gon is

$$A_n = \tfrac{1}{4} nc^2 \cot\left(\frac{\pi}{n}\right), \tag{9}$$

so the volumes of these frustums are

$$V_3 = \tfrac{1}{12}\sqrt{3}(a^2 + ab + b^2)h \tag{10}$$



$$V_4 = \tfrac{1}{3}(a^2 + ab + b^2)h. \tag{11}$$

Pyramidal Number

A FIGURATE NUMBER corresponding to a configuration of points which form a pyramid with r-sided REGULAR POLYGON bases can be thought of as a generalized pyramidal number, and has the form

$$P_n^r = \tfrac{1}{6}(n+1)(2p_n^r + n)$$
$$= \tfrac{1}{6}\, n(n+1)[(r-2)n + (5-r)]. \quad (1)$$

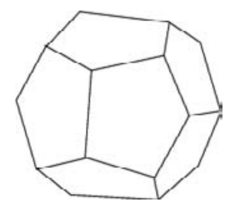
The first few cases are therefore

$$P_n^3 = \tfrac{1}{6}\, n(n+1)(n+2) \quad (2)$$

$$P_n^4 = \tfrac{1}{6}\, n(n+1)(2n+1) \quad (3)$$

$$P_n^5 = \tfrac{1}{2}\, n^2(n+1), \quad (4)$$

so $r=3$ corresponds to a TETRAHEDRAL NUMBER Te_n, and $r=4$ to a SQUARE PYRAMIDAL NUMBER P_n.



The pyramidal numbers can also be generalized to 4-D and higher dimensions (Sloane and Plouffe 1995).

Pythagoras's Constant

The number

$$\sqrt{2} = 1.4142135623\ldots,$$

which the Pythagoreans proved to be IRRATIONAL. This number is the length of the HYPOTENUSE of an ISOSCELES TRIANGLE with legs of length one, and the statement that it is IRRATIONAL means that it cannot be expressed as a ratio p/q of integers p and q.

Legend has it that the Pythagorean philosopher Hippasus used geometric methods to demonstrate the irrationality of $\sqrt{2}$ while at sea and, upon notifying his comrades of his great discovery, was immediately thrown overboard by the fanatic Pythagoreans .

Theodorus subsequently proved that the square roots of the numbers from 3 to 17 (excluding 4, 9, and 16) are also irrational (Wells 1986, p. 34).

The Babylonians gave the impressive approximation

$$\sqrt{2} \approx 1 + \frac{24}{60} + \frac{51}{60^2} + \frac{10}{60^3} = 1.41421296296296\ldots$$

(Wells 1986, p. 35; Guy 1990; Conway and Guy 1996, pp. 181–82).

Pythagoras's Theorem

Proves that the DIAGONAL d of a SQUARE with sides of integral length s cannot be RATIONAL. Assume d/s is rational and equal to p/q where p and q are INTEGERS with no common factors. Then

$$d^2 = s^2 + s^2 = 2s^2,$$

so

$$\left(\frac{d}{s}\right)^2 = \left(\frac{p}{q}\right)^2 = 2,$$

and $p^2 = 2q^2$, so p^2 is even. But if p^2 is EVEN, then p is EVEN. Since p/q is defined to be expressed in lowest terms, q must be ODD; otherwise p and q would have the common factor 2. Since p is EVEN, we can let $p \equiv 2r$, then $4r^2 = 2q^2$. Therefore, $q^2 = 2r^2$, and q^2, so q must be EVEN. But q cannot be both EVEN and ODD, so there are no d and s such that d/s is RATIONAL, and d/s must be IRRATIONAL.

In particular, PYTHAGORAS'S CONSTANT $\sqrt{2}$ is IRRATIONAL. Conway and Guy (1996) give a proof of this fact using paper folding, as well as similar proofs for ϕ (the GOLDEN RATIO) and $\sqrt{3}$ using a PENTAGON and HEXAGON.

Pythagorean Quadruple

POSITIVE INTEGERS a, b, c, and d which satisfy

$$a^2+b^2+c^2=d^2. \tag{1}$$

For POSITIVE EVEN a and b, there exist such INTEGERS c and d; for POSITIVE ODD a and b, no such INTEGERS exist (Oliverio 1996). Oliverio (1996) gives the following generalization of this result. Let $S=(a_1, \ldots, a_{n-2})$, where a_i are INTEGERS, and let T be the number of ODD INTEGERS in S. Then IFF $T \not\equiv 2$ (mod 4), there exist INTEGERS a_{n-1} and a_n such that

$$a_1^2+a_2^2+\ldots+a_{n-1}^2=a_n^2. \tag{2}$$

A set of Pythagorean quadruples is given by

$$a=2mp \tag{3}$$

$$b=2np \tag{4}$$

$$c=p^2-(m^2+n^2) \tag{5}$$

$$d=p^2+(m^2+n^2), \tag{6}$$

where m, n, and p are INTEGERS,

$$m+n+p\equiv 1 \pmod 2, \tag{7}$$

and

$$(m, n, p)=1 \tag{8}$$

(Mordell 1969). This does not, however, generate all solutions. For instance, it excludes (36, 8, 3, 37). Another set of solutions can be obtained from

$$a=2mp+2nq \tag{9}$$

$$b=2np-2mq \tag{10}$$

$$c=p^2+q^2-(m^2+n^2) \tag{11}$$

$$d=p^2+q^2+(m^2+n^2) \tag{12}$$

(Carmichael 1915).

q-Analog

A q-analog, also called a q-EXTENSION or q-GENERALIZATION, is a mathematical expression parameterized by a quantity q which generalizes a known expression and reduces to the known expression in the limit $q \to 1^+$. There are q-analogs of the FACTORIAL, BINOMIAL COEFFICIENT, DERIVATIVE, INTEGRAL, FIBONACCI NUMBERS, and so on. Koornwinder, Suslov, and Bustoz, have even managed some kind of q-Fourier analysis.

q-analogs are based on the observation that

$$\lim_{q\to 1^-}\frac{1-q^\alpha}{1-q}=\alpha,$$

so that the quantity $(1-q^\alpha)/(1-q)$ is sometimes written $[\alpha]$ (Koekoek and Swarttouw 1998, p. 7).

q-analogs also have a combinatorial interpretation based on the fact that one can count the elements of some set S to get the number $\#S$. A so-called "statistic" $f: S \to \mathbb{Z}$ can then be defined which is an integer-valued function on S and separates the elements of S into classes based on what value f takes on the elements. This relationship can be summarized by writing a polynomial in a new variable, usually taken as q, where the coefficient of q^n is $\#\{s\in S: f(s)=n\}$. Evaluating the polynomial at $q=1$ then adds the coefficients together, returning the original S.

The q-analog of a mathematical object is generally called the "q-object", hence q-BINOMIAL COEFFICIENT, q-FACTORIAL, etc. There are generally several q-analogs if there is one, and there is sometimes even a multibasic analog with independent q_1, q_2, ...

References

Nesterenko, Yu. V. *A Course on Algebraic Independence: Lectures at IHP 1999.* http://www.math.jussieu.fr/~nesteren/.

q-Beta Function

A q-ANALOG of the BETA FUNCTION

$$B(a,b)=\int_0^1 t^{a-1}(1-t)^{q-1}\mathrm{dt}=\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)},$$

where $\Gamma(z)$ is a GAMMA FUNCTION, is given by

$$B_q(a,b)\equiv\int_0^1 t^{b-1}(qt;q)_{a-1}d(a,t)=\frac{\Gamma_q(b)\Gamma_q(a)}{\Gamma_q(a+b)},$$

where $\Gamma_q(a)$ is a q-GAMMA FUNCTION and $(a;q)_n$ is a q-SERIES coefficient (Andrews 1986, pp. 11–12).

See also q-FACTORIAL, q-GAMMA FUNCTION

References

Andrews, G. E. q-Series: Their Development and Application in Analysis, Number Theory, Combinatorics, Physics, and Computer Algebra. Providence, RI: Amer. Math. Soc., 1986.

q-Binomial Coefficient

A q-ANALOG for the BINOMIAL COEFFICIENT, also called a GAUSSIAN COEFFICIENT or a Gaussian polynomial. a q-binomial coefficient is given by

$$\begin{bmatrix}n\\m\end{bmatrix}_q\equiv\frac{(q)_n}{(q)_m(q)_{n-m}}=\prod_{i=0}^{m-1}\frac{1-q^{n-i}}{1-q^{i+1}},\qquad(1)$$

where

$$(q)_k \equiv \prod_{m=1}^{\infty} \frac{1-q^m}{1-q^{k+m}} \tag{2}$$

is a Q-SERIES (Koepf 1998, p. 26). For $k, n \in \mathbb{N}$,

$$\begin{bmatrix} n \\ k \end{bmatrix}_q = \frac{[n]_q!}{[k]_q![n-k]_q!}, \tag{3}$$

where $[n]_q!$ is a Q-FACTORIAL (Koepf 1998, p. 30). The q-binomial coefficient can also be defined in terms of the Q-BRACKETS by

$$\begin{bmatrix} n \\ k \end{bmatrix}_q \equiv \begin{cases} \prod_{i=1}^{k} \frac{[n-i+1]_q}{[i]_q} & \text{for } 0 \leq k \leq n \\ 0 & \text{otherwise.} \end{cases} \tag{4}$$

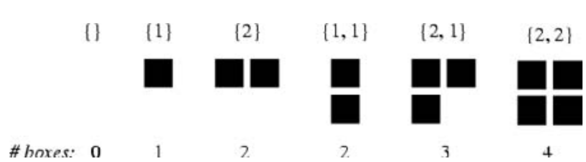
For $q \to 1^-$, the q-binomial coefficients turn into the usual BINOMIAL COEFFICIENT. The first few q-binomial coefficients are

$$\begin{bmatrix} 2 \\ 1 \end{bmatrix}_q = \frac{1-q^2}{1-q} = 1+q \tag{5}$$

$$\begin{bmatrix} 3 \\ 1 \end{bmatrix}_q = \begin{bmatrix} 3 \\ 2 \end{bmatrix}_q = \frac{1-q^3}{1-q} = 1+q+q^2 \tag{6}$$

$$\begin{bmatrix} 4 \\ 1 \end{bmatrix}_q = \begin{bmatrix} 4 \\ 3 \end{bmatrix}_q = \frac{1-q^4}{1-q} = 1+q+q^2+q^3 \tag{7}$$

$$\begin{bmatrix} 4 \\ 2 \end{bmatrix}_q = \frac{(1-q^3)(1-q^4)}{(1-q)(1-q^2)} = 1+q+2q^2+q^3+q^4. \tag{8}$$



From the definition, it follows that

$$\begin{bmatrix} n \\ 1 \end{bmatrix}_q = \begin{bmatrix} n \\ n-1 \end{bmatrix}_q = \sum_{i=0}^{n-1} q^i \tag{9}$$

Additional identities include

$$\frac{\begin{bmatrix} n+1 \\ k+1 \end{bmatrix}_q}{\begin{bmatrix} n \\ k+1 \end{bmatrix}_q} = \frac{1-q^{n+1}}{1-q^{n-k}} \tag{10}$$

$$\frac{\begin{bmatrix} n+1 \\ k+1 \end{bmatrix}_q}{\begin{bmatrix} n+1 \\ k \end{bmatrix}_q} = \frac{1-q^{n-k+1}}{1-q^{k+1}}. \tag{11}$$

The q-binomial coefficient $\begin{bmatrix} m+n \\ m \end{bmatrix}_q$ can be interpreted as a polynomial in q whose coefficient q^k counts the number of distinct partitions of k elements which fit inside an $m \times n$ rectangle. For example, the partitions of 1, 2, 3, and 4 are given in the following table.

n	partitions
0	{ }
1	{{1}}
2	{{2}, {1, 1}}
3	{{3}, {2, 1}, {1, 1, 1}}
4	{{4}, {3, 1}, {2, 2}, {2, 1, 1}, {1, 1, 1, 1},}

Of these, { }, {1}, {2}, {1,1}, {2,1}, and {2,2} fit inside a 2×2 box. The counts of these having 0, 1, 2, 3, and 4 elements are 1, 1, 2, 1, and 1, so the (4, 2)-binomial coefficient is given by

$$\begin{bmatrix} 4 \\ 2 \end{bmatrix}_q = 1+q+2q^2+q^3+q^4, \tag{12}$$

as above.

q-Binomial Theorem

The Q-ANALOG of the BINOMIAL THEOREM

$$(1-z)^n = 1 - nz + \frac{n(n-1)}{1 \cdot 2} z^2 - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} z^3 + \ldots$$

is given by

$$\left(1-\frac{z}{q^n}\right)\left(1-\frac{z}{q^{n-1}}\right)\cdots\left(1-\frac{z}{q}\right)$$
$$= 1 - \frac{1-q^n}{1-q}\frac{z}{q^n} + \frac{1-q^n}{1-q}\frac{1-q^{n-1}}{1-q^2}\frac{z^2}{q^{n+(n-1)}}$$
$$- \ldots \pm \frac{z^n}{q^{n(n+1)/2}}.$$

Written as a Q-SERIES, the identity becomes

$$\sum_{n=0}^{\infty} \frac{(a;q)_n}{(q;q)_n} z^n = \frac{(az;q)_\infty}{(z;q)_\infty},$$

where

$$(a;q)_n = \prod_{m=0}^{\infty} \frac{(1-aq^m)}{(1-aq^{m+n})}$$

(Heine 1847, p. 303; Andrews 1986). The CAUCHY BINOMIAL THEOREM is a special case of this general theorem.

q-Chu-Vandermonde Identity

A q-ANALOG of the CHU-VANDERMONDE IDENTITY given by

$${}_2\phi_1(q^{-n},b;c;q,cq^n/b) = \frac{(cq^n;q)_\infty (c/b;q)_\infty}{(c;q)_\infty (cq^n/b;q)_\infty} = \frac{(c/b;q)_n}{(c;q)_n},$$

where ${}_2\phi_1(a,b;c;q,z)$ is the q-HYPERGEOMETRIC FUNCTION. The identity can also be written as

$${}_2\phi_1(q^{-n},b;c;q,q) = \frac{(c/b;q)_n}{(c;q)_n} b^n$$

See also CHU-VANDERMONDE IDENTITY, q-HYPERGEOMETRIC FUNCTION

References

q-Cosine

A q-ANALOG of the COSINE function, as advocated by R. W. Gosper, is defined by

$$\cos_q(z,q) = \frac{\vartheta_2(z,p)}{\vartheta_2(0,p)}, \tag{1}$$

where $\vartheta_2(z,p)$ is a JACOBI THETA FUNCTION and p is defined via

$$(\ln p)(\ln q) = \pi^2. \tag{2}$$

This is a period 2π, EVEN FUNCTION of unit amplitude with double and triple angle formulas and addition formulas which are analogous to ordinary SINE and COSINE. For example,

$$\cos_q(2z,q) = \cos_q^2(z,q^2) - \sin_q^2(z,q^2), \tag{3}$$

where $\sin_q(z,a)$ is the q-SINE, and π_q is q-PI. The q-cosine also satisfies

$$\cos_q(\pi a) = \frac{\sum_{n=-\infty}^{\infty} (-1)^n q^{(n+a)^2}}{\sum_{n=-\infty}^{\infty} (-1)^n q^{n^2}}. \tag{4}$$

See also q-FACTORIAL, q-SINE

References

Gosper, R. W. "Experiments and Discoveries in q-Trigonometry." Unpublished manuscript.

q-Derivative

The q-ANALOG of the DERIVATIVE, defined by

$$\left(\frac{d}{dx}\right)_q f(x) = \frac{f(x)-f(qx)}{x-qx}.$$

For example,

$$\left(\frac{\mathrm{d}}{\mathrm{dx}}\right)_q \sin x = \frac{\sin x - \sin(qx)}{x - qx}$$

$$\left(\frac{\mathrm{d}}{\mathrm{dx}}\right)_q \ln x = \frac{\ln x - \ln(qx)}{x - qx} = \frac{\ln\left(\frac{1}{q}\right)}{(1-q)x}$$

$$\left(\frac{\mathrm{d}}{\mathrm{dx}}\right)_q x^2 = \frac{x^2 - q^2x^2}{x - qx} = (1+q)x$$

$$\left(\frac{\mathrm{d}}{\mathrm{dx}}\right)_q x^3 = \frac{x^3 - q^3x^3}{x - qx} = (1+q+q^2)x^2.$$

In the LIMIT $q \to 1$, the q-derivative reduces to the usual DERIVATIVE.

See also DERIVATIVE

q-Dimension

$$D_q \equiv \frac{1}{1-q} \lim_{\varepsilon \to 0} \frac{\ln I(q, \varepsilon)}{\ln\left(\frac{1}{\varepsilon}\right)} \tag{1}$$

where

$$I(q, \varepsilon) \equiv \sum_{i=1}^{N} \mu_i^q, \tag{2}$$

ε is the box size, and μ_i is the NATURAL MEASURE. The CAPACITY DIMENSION (a.k.a. box-counting dimension) is given by $q = 0$,

$$D_0 = \frac{1}{1-0} \lim_{\varepsilon \to 0} \frac{\ln\left(\sum_{i=1}^{N(\varepsilon)} 1\right)}{-\ln \varepsilon} = -\lim_{\varepsilon \to 0} \frac{\ln[N(\varepsilon)]}{\ln \varepsilon} \tag{3}$$

If all μ_is are equal, then the CAPACITY DIMENSION is obtained for any q.

The INFORMATION DIMENSION corresponds to $q = 1$ and is given by

$$D_1 = \lim_{q \to 1} D_q = \lim_{q \to 1} \frac{\lim_{\varepsilon \to 0} \frac{\ln\left[\sum_{i=1}^{N(\varepsilon)} \mu_i^q\right]}{-\ln \varepsilon}}{1-q}$$

$$= \lim_{\varepsilon \to 0} \lim_{q \to 1} \frac{\ln\left[\sum_{i=1}^{N(\varepsilon)} \mu_i^q\right]}{(q-1) \ln \varepsilon}. \tag{4}$$

But for the numerator,

$$\lim_{q \to 1} \ln\left(\sum_{i=1}^{N(\varepsilon)} \mu_i^q\right) = \ln\left(\sum_{i=1}^{N(\varepsilon)} \mu_i\right) = \ln 1 = 0, \tag{5}$$

and for the denominator, $\lim_{q \to 1}(q-1) = 0$, so use L'HOSPITAL'S RULE to obtain

$$D_1 = \lim_{\varepsilon \to 0}\left(\frac{1}{\ln \varepsilon} \lim_{q \to 1} \frac{\sum \mu_i^q \ln \mu_i}{1}\right). \tag{6}$$

Therefore,

$$D_1 = \lim_{\varepsilon \to 0}\left(\frac{\sum_{i=1}^{N(\varepsilon)} \mu_i \ln \mu_i}{\ln \varepsilon}\right) \tag{7}$$

(Ott 1993, p. 79).

D_2 is called the CORRELATION DIMENSION.

If $q_1 > q_2$, then

$$D_{q_1} \le D_{q_2} \tag{8}$$

(Ott 1993, p. 79).

q-Extension

q-ANALOG

q-Factorial

The q-ANALOG of the FACTORIAL (by analogy with the q-GAMMA FUNCTION). For a an integer, the q-factorial is defined by

$$[k]_q! = \text{faq}(k,q) = 1(1+q)(1+q+q^2)\cdots(1+q+\ldots+q^{k-1}) \quad (1)$$

$$= \frac{(q;q)_k}{(1-q)^k} \quad (2)$$

(Koepf 1998, p. 26). For $k \in \mathbb{N}$,

$$[k]_q! = \Gamma_q(k+1), \quad (3)$$

where $\Gamma_q(k+1)$ is the q-GAMMA FUNCTION. The first few values are

$$[1]_q! = 1$$

$$[2]_q! = 1+q$$

$$[3]_q! = (1+q)(1+q+q^2) = 1+2q+2q^2+q^3$$

$$[4]_q! = (1+q)(1+q+q^2)(1+q+q^2+q^3) = 1+3q+5q^2+6q^3+5q^4+3q^5+q^6.$$

A reflection formula analogous to the GAMMA FUNCTION reflection formula is given by

$$\cos_q(\pi a) = \sin_q\left[\pi\left(\tfrac{1}{2}-a\right)\right] = \frac{\pi_q q^{(a-1/2)(a+1/2)}}{\text{faq}\left(a-\tfrac{1}{2},q^2\right)\text{faq}\left(-\left(a+\tfrac{1}{2}\right),q^2\right)}, \quad (4)$$

where $\cos_q(z)$ is the q-COSINE, $\sin_q(z)$ is the q-SINE, and π_q is q-PI.

Q-Function

Let

$$q = e^{-\pi K'/K} = e^{-i\pi\tau}, \quad (1)$$

then

$$Q_0 \equiv \prod_{n=1}^{\infty}(1-q^{2n}) \quad (2)$$

$$Q_1 \equiv \prod_{n=1}^{\infty}(1+q^{2n}) \quad (3)$$

$$Q_2 \equiv \prod_{n=1}^{\infty}(1+q^{2n-1}) \quad (4)$$

$$Q_3 \equiv \prod_{n=1}^{\infty}(1-q^{2n-1}). \quad (5)$$

The Q-functions are sometimes written using a lower-case q instead of a capital Q. The Q-functions also satisfy the identities

$$Q_0Q_1 = Q_0(q^2) \quad (6)$$

$$Q_0Q_3 = Q_0(q^{1/2}) \quad (7)$$

$$Q_2Q_3 = Q_3(q^2) \quad (8)$$

$$Q_1Q_2 = Q_1(q^{1/2}). \quad (9)$$

The NORMAL DISTRIBUTION FUNCTION $\Phi(x)$ is sometimes also denoted $Q(x)$.

q-Gamma Function

A q-ANALOG of the GAMMA FUNCTION defined by

$$\Gamma_q(x) \equiv \frac{(q;q)_\infty}{(q^x;q)_\infty}(1-q)^{1-x}, \quad (1)$$

where $(x,q)_\infty$ is a q-SERIES (Koepf 1998, p. 26; Koekoek and Swarttouw 1998). The q-gamma function satisfies

$$\lim_{q\to 1^-}\Gamma_q(x) = \Gamma(x) \quad (2)$$

where $\Gamma(z)$ is the GAMMA FUNCTION, (Andrews 1986).

The q-gamma function satisfies the functional equation

$$\Gamma_q(z+1) = \frac{1-q^z}{1-q}\Gamma_q(z) \quad (3)$$

with $\Gamma_q(1)$ (Koekoek and Swarttouw 1998), which

simplifies to

$$\Gamma(z+1) = z\Gamma(z) \tag{4}$$

as $q \to 1^-$. A curious identity for the functional equation

$$f(a-b)f(a-c)f(a-d)f(a-e) - f(b)f(c)f(d)f(e)$$
$$= q^b f(a)f(a-b-c)f(a-b-d)f(a-b-e), \tag{5}$$

where

$$b+c+d+e = 2a \tag{6}$$

is given by

$$f(\alpha) = \begin{cases} \sin(k\alpha) & \text{for } q=1 \\ \dfrac{1}{\Gamma_q(\alpha)\Gamma_q(1-\alpha)} & \text{for } 0<q<1, \end{cases} \tag{7}$$

for any k.

q-Gauss Identity

A q-ANALOG of Gauss's theorem due to Jacobi and Heine,

$${}_2\phi_1(a,b;c;q,c/(ab)) = \frac{(c/a;q)_\infty (c/b;q)_\infty}{(c;q)_\infty (c/(ab);q)_\infty} \tag{1}$$

for $|c/(ab)|<1$ (Gordon and McIntosh 1997; Koepf 1998, p. 40), where ${}_2\phi_1(a,b;c;q,z)$ is a q-HYPERGEOMETRIC SERIES. A special case for $a = q^{-n}$ is given by

$$\sum_{k=0}^n q^{k^2} \begin{bmatrix} n \\ k \end{bmatrix}_q^2 = \frac{(\sqrt{q};q)_n(-\sqrt{q};q)_n(-q;q)_n}{(q;q)_n},$$

where $\begin{bmatrix} n \\ k \end{bmatrix}_q$ is a q-BRACKET (Koepf 1998, p. 43).

q-Generalization

q-ANALOG

q-Harmonic Series

The series

$$h_q(-r) = \sum_{n=1}^\infty \frac{1}{q^n + r} \tag{1}$$

for q an INTEGER other than 0 and ± 1 which is the q-ANALOG of

$$H_n = \sum_{n=1}^\infty \frac{1}{n}. \tag{2}$$

h_q and the related series

$$Ln_q(-r+1) = \sum_{n=1}^\infty \frac{(-1)^n}{q^n + r}, \tag{3}$$

which is a q-extension of the NATURAL LOGARITHM ln 2, are irrational for r a RATIONAL NUMBER other than 0 or $-q^n$ (Guy 1994). In fact, Amdeberhan and Zeilberger (1998) showed that the IRRATIONALITY MEASURES of both $h_q(1)$ and $Ln_q(2)$ are 4.80, improving the value of 54.0 implied by Borwein (1991, 1992).

Amdeberhan and Zeilberger (1998) also show that the q-harmonic series and q-extension of ln 2 can be written in the more quickly converging forms

$$h_q(1) = \sum_{n=1}^\infty \frac{q^n}{(1-q^n)(q)_n} \tag{4}$$

$$= \sum_{n=1}^\infty \frac{1-q^n-q^{2n}}{(q^n-1)\binom{2n}{n}_q (q)_n} \tag{5}$$

$$Ln_q(2) = \sum_{n=1}^\infty \frac{q^n (q)_n}{(1-q^n)(q^2)_n} \tag{6}$$

$$= \sum_{n=1}^\infty \frac{(-1)^{n-1}(q)_n(1-q^{3n})}{(1-q^n)^2 \binom{2n}{n}_q (q^2)_n}, \tag{7}$$

where $\binom{n}{k}_q$ is a q-BINOMIAL COEFFICIENT and

$$(q)_n = (1-q)(1-q^2)\cdots(1-q^n) \quad (8)$$

for $n \geq 1$.

q-Hypergeometric Function

The modern definition of the q-hypergeometric function is

$$ {}_r\phi_s\left[\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_r\\ \beta_1,\ldots\beta_s\end{matrix};q,z\right] \equiv \sum_{n=0}^\infty \frac{(\alpha_1;q)_n(\alpha_2;q)_n\ldots(\alpha_r;q)_n}{(\beta_1;q)_n\ldots(\beta_s;q)_n}\frac{z^n}{(q;q)_n} \times\left[(-1)^n q^{\binom{n}{2}}\right]^{1+s-r}, \quad (1)$$

where $\binom{n}{2} = \frac{1}{2}n(n-1)$ is a binomial coefficient and $(a;q)_n$ is a q-Pochhammer symbol

$$(a;q)_n = (1-a)(1-aq)(1-aq^2)\cdots(1-aq^{n-1}) \quad (2)$$

$$(a;q)_0 = 1 \quad (3)$$

(Gasper and Rahman 1990; Bhatnagar 1995, p. 21; Koepf 1998, p. 25).

An old-fashioned definition omits the factor $[(-1)^k q^{\binom{n}{2}}]^{1+s-r}$,

$$ {}_r\phi'_s\left[\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_r\\ \beta_1,\ldots,\beta_s\end{matrix};q,z\right] \equiv \sum_{n=0}^\infty \frac{(\alpha_1;q)_n(\alpha_2;q)_n\ldots(\alpha_r;q)_n}{(\beta_1;q)_n\ldots(\beta_s;q)_n}\frac{z^n}{(q;q)_n}, \quad (4)$$

This is the q-hypergeometric function as defined by Bailey (1935), Slater (1966), Andrews (1986), and Hardy (1999).

A particular case of ${}_r\phi'_s$ is given by

$$ {}_2\psi'_1(a,b;c;q,z) = \sum_{n=0}^\infty \frac{(a;q)_n(b;q)_n z^n}{(q;q)_n(c;q)_n} \quad (5)$$

(Andrews 1986, p. 10). A q-analog of Gauss's theorem (the q-Gauss identity) due to Jacobi and Heine is given by

$$ {}_2\phi'_1(a,b;c;q,c/(ab)) = \frac{(c/a;q)_\infty(c/b;q)_\infty}{(c;q)_\infty(c/(ab);q)_\infty} \quad (6)$$

for $|c/(ab)| < 1$ (Koepf 1998, p. 40). Heine proved the transformation formula

$$ {}_2\phi'_1(a,b;c;q,z) = \frac{(b;q)_\infty(az;q)_\infty}{(c;q)_\infty(z;q)_\infty}\,{}_2\phi_1(c/b_2a;az;q,b), \quad (7)$$

(Andrews 1986, pp. 10–11). Rogers (1893) obtained the formulas

$$ {}_2\phi'_1(a,b;c;q,z) = \frac{(c/b;q)_\infty(bz;q)_\infty}{(z;q)_\infty(c;q)_\infty}\,{}_2\phi_1(b,abz/c;bz;q,c/b) \quad (8)$$

$$ {}_2\phi'_1(a,b,c;q,z) = (abz/c;q)_\infty(z;q)_\infty\,{}_2\phi 1(c/a,c/b;c;q,abz/c) \quad (9)$$

(Andrews 1986, pp. 10–11).

The function ${}_r\phi_s$ has the simple confluent identity

$$\lim_{\alpha_r\to\infty} {}_r\phi_s\left[\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_r\\ \beta_1,\ldots,\beta_s\end{matrix};q,\frac{z}{\alpha_r}\right] = \left[\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_{r-1}\\ \beta_1,\ldots,\beta_s\end{matrix};q,z\right]. \quad (10)$$

In the limit $q \to 1^-$,

$$\lim_{q\to 1^-} {}_r\phi_s\left[\begin{matrix}q^{\alpha_1}q^{\alpha_2},\ldots,q^{\alpha_r}\\ q^{\beta_1},\ldots,q^{\beta_s}\end{matrix};q,(q-1)^{1+s-r}z\right] = {}_rF_s\left[\begin{matrix}\alpha_1,\alpha_2,\ldots,\alpha_r\\ \beta_2,\ldots,\beta_s\end{matrix};z\right], \quad (11)$$

where ${}_rF_s$ is a generalized hypergeometric function (Koepf 1998, p. 25).

q-Hypergeometric Series

q-HYPERGEOMETRIC FUNCTION

q-Integral

A q-analog of integration

$$\int_q \Phi(x)d(qx)$$

which reduces to

$$\int \Phi(x)dx$$

in the case $q=1$. A specific case gives

$$\int_{0_q}^{\infty}\frac{x^{a-1}}{1-x}d(qx)=\frac{\left[\Gamma_q\left(\frac{1}{2}\right)\right]^2}{\sigma_q(a)},$$

where Γ_q is the q-Gamma function and σ_q is a doubly periodic sigma function. If $q=1$, the integral reduces to

$$\int_0^{\infty}\frac{x^{a-1}}{1-x}\,dx=\frac{\pi}{\sin(\pi a)}.$$

Q-Matrix

FIBONACCI *Q*-MATRIX

q-Multinomial Coefficient

A *q*-ANALOG of the MULTINOMIAL COEFFICIENT, defined as

$$\frac{[a_1+\ldots+a_n]!}{[a_1]!\ldots[a_n]!},$$

where

$$[n]!\equiv(1)(1+q)\cdots(1+q+\ldots+q^{n-1}).$$

See also MULTINOMIAL COEFFICIENT, ZEILBERGER-BRESSOUD THEOREM

Q-Number

HOFSTADTER'S *Q*-SEQUENCE

q-Pfaff-Saalschuetz Sum

q-SAALSCHUETZ SUM

q-Pi

The *q*-ANALOG of PI π_q can be defined by taking $a=0$ in the *q*-FACTORIAL

$$\text{faq}(a,q)=1(1+q)(1+q+q^2)\cdots(1+q+\ldots+q^{a-1}),$$

giving

$$1=\sin_q\left(\tfrac{1}{2}\pi\right)=\frac{\pi_q}{\text{faq}^2\left(-\frac{1}{2},q^2\right)q^{1/4}},$$

where $\sin_q(z)$ is the *q*-SINE. Gosper has developed an iterative algorithm for computing π_q based on the algebraic RECURRENCE RELATION

$$\frac{4\pi_{q^4}}{q^{4+1}}\frac{(q^2+1)^2\pi_q^2}{\pi_{q^2}}-\frac{(q^4+1)\pi_{q^2}^2}{\pi_{q^4}}$$

q-Pochhammer Symbol

The *q*-ANALOG of the POCHHAMMER SYMBOL defined by

$$(a;q)k=\begin{cases}\prod_{j=0}^{k-1}(1-aq^j) & \text{if } k>0\\ 1 & \text{if } k=0\\ \prod_{j=0}^{k}(1-aq^{-j})^{-1} & \text{if } k<0\\ \prod_{j=0}^{\infty}(1-aq^j) & \text{if } k=\infty\end{cases}\quad(1)$$

(Koepf 1998, p. 25). q-Pochhammer symbols are frequently called *q*-SERIES and, for brevity, $(a;q)_k$ is often simply written $(a)_k$.

For $q \to 1^-$,

$$\lim_{q\to 1^-} \frac{(q^\alpha;q)_k}{(1-q)^k} = (\alpha)_k \tag{2}$$

gives the normal POCHHAMMER SYMBOL $(\alpha)_n$ (Koekoek and Swarttouw 1998, p. 7). The q-Pochhammer symbols are also called q-shifted factorials (Koekoek and Swarttouw 1998, pp. 8–9).

The q-Pochhammer symbol satisfies

$$(a;q)_n = \frac{(a;q)_\infty}{(aq^n;q)_\infty} \tag{3}$$

$$\frac{1-aq^{2n}}{1-a} = \frac{(q\sqrt{a};q)_n(-q\sqrt{a};q)_n}{(\sqrt{a};q)_n(-\sqrt{a};q)_n} \tag{4}$$

$$(a;q)_n(-a;q)_n = (a^2;q^2)_n$$

$$(a;q)_n = (q^{1-n}/a;q)_n(-a)^n q^{\binom{n}{2}} \tag{5}$$

$$(a;q^{-1})_n = (a^{-1};q)_n(-a)^n q^{-\binom{n}{2}} \tag{6}$$

$$(a;q)_{-n} = \frac{1}{(aq^{-n};q)_n} = \frac{(-q/a)^n}{(q/a;q)_n} q^{\binom{n}{2}}, \tag{7}$$

where $\binom{n}{2}$ is a BINOMIAL COEFFICIENT and

$$\binom{n}{2} = \tfrac{1}{2}n(n-1), \tag{8}$$

as well as many other identities, some of which are given by Koekoek and Swarttouw (1998, p. 9).

A generalized q-Pochhammer symbol can be defined using the concise notation

$$(a_1,a_2,\ldots,a_r;q)_\infty = (a_1;q)_\infty(a_2;q)_\infty\cdots(a_r;q)_\infty \tag{9}$$

(Gordon and McIntosh 2000).

Q-Polynomial

BLM/HO POLYNOMIAL

q-Product

Q-FUNCTION

QR Decomposition

Given a MATRIX A, its QR-decomposition is OF THE FORM

$$\mathsf{A} = \mathsf{QR},$$

where R is an upper TRIANGULAR MATRIX and Q is an ORTHOGONAL MATRIX, i.e., one satisfying

$$\mathsf{Q}^\mathrm{T}\mathsf{Q} = \mathsf{I}$$

where I is the IDENTITY MATRIX. This matrix decomposition can be used to solve linear systems of equations. QR decomposition is implemented in *Mathematica* as `QRDecomposition[m]`.

q-Saalschuetz Sum

A q-analog of the Saalschütz theorem due to Jackson is given by

$$\begin{aligned}&{}_3\phi_2(q^{-n},a,b;c;ab/(cq^{n-1});q,q)\\&= \frac{(c/a;q)_n(c/b;q)_n}{(c,q)_n(c/(ab);q)_n}\end{aligned} \tag{1}$$

where ${}_3\phi_2$ is the q-HYPERGEOMETRIC FUNCTION (Koepf 1998, p. 40; Schilling and Warnaar 1999).

See also q-HYPERGEOMETRIC FUNCTION

q-Series

A SERIES involving coefficients OF THE FORM

$$(a;q)_n \equiv (a)_n = \prod_{k=0}^{n-1}(1-aq^k) \tag{1}$$

$$= \prod_{k=0}^{\infty}\frac{(1-aq^k)}{(1-aq^{k+n})} \tag{2}$$

$$= \frac{(a;q)_\infty}{(aq^n;q)_\infty} \tag{3}$$

for $n \geq 1$, also called a q-POCHHAMMER SYMBOL (Andrews 1986, p. 10). The notation

$$(q)_n \equiv (q;q)_n = \prod_{k=1}^{n-1}(1-q^k) \tag{4}$$

is also used (Hirschhorn 1999). The symbol for $n \to \infty$ is defined as

$$(a)_\infty \equiv (a;q)_\infty = \prod_{k=0}^{\infty}(1-aq^k), \tag{5}$$

giving the special case

$$\eta(\tau) = (q;q)_\infty = q^{1/24}\prod_{k=0}^{\infty}(1-q\cdot q^k)$$

$$= q^{1/24}\prod_{k=1}^{\infty}(1-q^k), \tag{6}$$

where $q \equiv e^{2\pi ir}$ and $\eta(\tau)$ is called the DEDEKIND ETA FUNCTION.

Identities involving $(q)_\infty$ include

$$(q)_\infty^3 = \sum_{n=0}^{\infty}(-1)^n(2n+1)q^{n(n+1)/2} \tag{7}$$

$$= X + 2qY \tag{8}$$

(Hardy and Wright 1979, Hirschhorn 1999), where

$$X = \prod_{n=1}^{\infty}(1-q^{25n-15})(1-q^{25n-10})(1-q^{25n})$$

$$= \sum_{-\infty}^{\infty}(-1)^n q^{(25n^2-5n)/2} \tag{9}$$

$$Y = \prod_{n=1}^{\infty}(1-q^{25n-30})(1-q^{25n-5})(1-q^{25n})$$

$$= \sum_{-\infty}^{\infty}(-1)^n q^{(25n^2-15n)/2} \tag{10}$$

(Hirschhorn 1999)

The symbols

$$[n] \equiv 1 + q + q^2 + \ldots + q^{n-1} \tag{11}$$

$$[n]! \equiv [n][n-1]\cdots[1] \tag{12}$$

are sometimes also used when discussing q-series.

There are a great many other beautiful identities involving q-series, some of which follow directly by taking the q-ANALOG of standard combinatorial identities, e.g., the q-BINOMIAL THEOREM

$$\sum_{n=0}^{\infty}\frac{(a;q)_n z^n}{(q;q)_n} = \frac{(az;q)_\infty}{(z;q)_\infty} \tag{13}$$

($|z| < 1$, $|q| < 1$; Andrews 1986, p. 10), a special case of an identity due to Euler

$$(aq;q)_\infty = \sum_{k=0}^{\infty}\frac{(-1)^k q^{k(k+1)/2}a^k}{(c;q)_k} \tag{14}$$

(Gasper and Rahman 1990, p. 9; Leininger and Milne 1997), and q-VANDERMONDE SUM

$${}_2\phi_1(a,q^{-n};c;q,q) = \frac{a^n(c/a,q)_n}{(c;q)_n}, \tag{15}$$

where ${}_2\phi_1(a,b;c;q,z)$ is a q-HYPERGEOMETRIC SERIES. Other q-series identities, e.g., the JACOBI IDENTITIES, ROGERS-RAMANUJAN IDENTITIES, and q-HYPERGEOMETRIC identity

$${}_2\phi_1(a,b;c;q,z)$$

$$= \frac{(b;q)_\infty(az;q)_\infty}{(c;q)_\infty(z;q)_\infty}\,{}_2\phi_1(c/b,a;az;q,b), \tag{16}$$

seem to arise out of the blue. Another such example is

$$\sum_{n=0}^{\infty}\frac{(-q;q^2)_n q^{n(n-1)}z^n}{(z;q^2)_n} = \sum_{n=0}^{\infty}\frac{(-zq;q^4)_n q^{n(2n-1)}z^n}{(z;q^2)_{2n+1}} \tag{17}$$

(Gordon and McIntosh 2000).

Asymptotic results for q-series include

$$(q)_\infty = \sqrt{\frac{2\pi}{t}}\exp\left(-\frac{\pi^2}{6t}+\frac{t}{24}\right) + \iota(1) \tag{18}$$

$$(q^2;q^2)_\infty = \sqrt{\frac{\pi}{t}}\exp\left(-\frac{\pi^2}{12t}+\frac{t}{12}\right) + \iota(1) \tag{19}$$

$$(q;q^2)_\infty = \frac{(q)_\infty}{(q^2;q^2)_\infty} = \sqrt{2}\,\exp\left(-\frac{\pi^2}{12t}-\frac{t}{24}\right)+\iota(1) \quad (20)$$

(Watson 1936, Gordon and McIntosh 2000).

q-Shifted Factorial

q-Pochhammer Symbol

Q-Signature

Signature (Recurrence Relation)

q-Sine

The q-analog of the sine function, as advocated by R. W. Gosper, is defined by

$$\sin_q(z,q) = \frac{\vartheta_1(z,p)}{\vartheta_1\left(\frac{1}{2}\pi,p\right)},$$

where $\vartheta_1(z,p)$ is a Jacobi theta function and p is defined via

$$(\ln p)(\ln q) = \pi^2.$$

This is a period 2π, odd function of unit amplitude with double and triple angle formulas and addition formulas which are analogous to ordinary sine and cosine. For example,

$$\sin_q(2z,q) = (q+1)\frac{\pi_q}{P_{q^2}}\cos_q(z,q^2)\,\sin_q(z,q^2),$$

where $\cos_q(z,a)$ is the q-cosine, and π_q is q-pi.

Quadrable

A plane figure for which quadrature is possible is said to be quadrable.

Quadrangle

A plane figure consisting of four points, each of which is joined to two other points by a line segment (where the line segments may intersect). A quadrangle may therefore be concave or convex; if it is convex, it is called a quadrilateral.

Quadratfrei

SQUAREFREE

Quadratic Congruence Equation

A CONGRUENCE OF THE FORM

$$ax^2 + bx + c \equiv 0 \pmod{m},$$

where a, b, and c are INTEGERS. A general quadratic congruence can be reduced to the congruence

$$x^2 \equiv q \pmod{p}$$

and can be solved using EXCLUDENTS, although solution of the general polynomial congruence

$$a_m x^m + \ldots + a_2 x^2 + a_1 x + a_0 \equiv 0 \pmod{n}$$

is intractable.

See also CONGRUENCE, CONGRUENCE EQUATION, EXCLUDENT, LINEAR CONGRUENCE EQUATION

Quadratic Curve

The general bivariate quadratic curve can be written

$$ax^2 + 2bxy + cy^2 + 2dx + 2fy + g = 0. \tag{1}$$

Define the following quantities:

$$\Delta = \begin{vmatrix} a & b & d \\ b & c & f \\ d & f & g \end{vmatrix} \tag{2}$$

$$J = \begin{vmatrix} a & b \\ b & c \end{vmatrix} \tag{3}$$

$$I = a + c \tag{4}$$

$$K = \begin{vmatrix} a & d \\ d & g \end{vmatrix} + \begin{vmatrix} c & f \\ f & g \end{vmatrix}. \tag{5}$$

Then the quadratics are classified into the types summarized in the following table (Beyer 1987). The real (nondegenerate) quadratics (the ELLIPSE, HYPERBOLA, and PARABOLA) correspond to the curves which can be created by the intersection of a PLANE with a (two-NAPPES) CONE, and are therefore known as CONIC SECTIONS.

Curve	Δ	J	Δ/I	K
Coincident Lines	0	0		0
Ellipse (Imaginary)	$\neq 0$	>0	>0	
ELLIPSE (Real)	$\neq 0$	>0	<0	
HYPERBOLA	$\neq 0$	<0		
Intersecting Lines (Imaginary)	0	>0		
Intersecting Lines (Real)	0	<0		
PARABOLA	$\neq 0$	0		
Parallel Lines (Imaginary)	0	0		>0
Parallel Lines (Real)	0	0		<0

It is always possible to eliminate the xy cross term by a suitable ROTATION of the axes. To see this, consider rotation by an arbitrary angle θ. The ROTATION MATRIX is

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} x'\cos\theta + y'\sin\theta \\ -x'\sin\theta + y'\cos\theta \end{bmatrix}, \tag{6}$$

so

$$x = x'\cos\theta + y'\sin\theta \tag{7}$$

$$y = -x'\sin\theta + y'\cos\theta \tag{8}$$

$$xy = -x'^2\cos\theta\sin\theta + x'y'(\cos^2\theta - \sin^2\theta) + y'^2\cos\theta\sin\theta \tag{9}$$

$$x^2 = x'^2\cos^2\theta + 2x'y'\cos\theta\sin\theta + y'^2\sin^2\theta \tag{10}$$

$$y^2 = -x'^2\sin^2\theta - 2x'y'\sin\theta\cos\theta + y'^2\cos^2\theta. \tag{11}$$

Plugging these into (1) gives

$$a(x'^2\cos^2\theta + 2x'y'\cos\theta + y'^2\sin^2\theta)$$

$$+2b(x'\cos\theta + y'\sin\theta) - (-x'\sin\theta + y'\cos\theta)$$

$$+c\left(x'^2 \sin^2\theta - 2x'y' \cos\theta \sin\theta + y'^2 \cos^2\theta\right)$$

$$+2d(x' \cos\theta + y' \sin\theta)$$

$$+2f(-x' \sin\theta + y' \cos\theta) + g = 0. \quad (12)$$

$$a\left(x'^2 \cos^2\theta + 2x'y' \cos\theta + y'^2 \sin^2\theta\right)$$

$$+2b\left(-x^2 \cos^2\theta \sin\theta - xy \sin^2\theta + xy \cos^2\theta + y^2 \cos\theta \sin\theta\right)$$

$$+c\left(x'^2 \sin^2\theta - 2x'y' \cos\theta \sin\theta + y'^2 \cos^2\theta\right)$$

$$+2d(x' \cos\theta + y' \sin\theta)$$

$$+2f(-x' \sin\theta + y' \cos\theta) + g = 0. \quad (13)$$

Grouping terms,

$$x'^2\left(a \cos^2\theta + c \sin^2\theta - 2b \cos\theta \sin\theta\right)$$

$$+x'y'\left[2a \cos\theta \sin\theta - 2c \sin\theta \cos\theta + 2b\left(\cos^2\theta - \sin^2\theta\right)\right]$$

$$+y'^2\left(a \sin^2\theta + c \cos^2\theta + 2b \cos\theta \sin\theta\right)$$

$$+x'(2d \cos\theta - 2f \sin\theta) + y'(-2d \sin\theta + 2f \cos\theta)$$

$$+g = 0. \quad (14)$$

Comparing the COEFFICIENTS with (1) gives an equation OF THE FORM

$$a'x'^2 + 2b'x'y' + c'y'^2 + 2d'x' + 2f'y' + g' = 0, \quad (15)$$

where the new COEFFICIENTS are

$$a' = a \cos^2\theta - 2b \cos\theta \sin\theta + c \sin^2\theta \quad (16)$$

$$b' = b\left(\cos^2\theta - \sin^2\theta\right) + (a - c) \sin\theta \cos\theta \quad (17)$$

$$c' = a \sin^2\theta + 2b \sin\theta \cos\theta + c \cos^2\theta \quad (18)$$

$$d' = d \cos\theta - f \sin\theta \quad (19)$$

$$f' = -d \sin\theta + f \cos\theta \quad (20)$$

$$g' = g. \quad (21)$$

The cross term $2b'x'y'$ can therefore be made to vanish by setting

$$b' = b(\cos^2\theta - \sin^2\theta) - (c - a) \sin\theta \cos\theta$$

$$= b \cos(2\theta) - \tfrac{1}{2}(c - a) \sin(2\theta) = 0. \quad (22)$$

For b' to be zero, it must be true that

$$\cos(2\theta) = \frac{c - a}{2b} \equiv K. \quad (23)$$

The other components are then given with the aid of the identity

$$\cos\left[\cot^{-1}(x)\right] = \frac{x}{\sqrt{1 + x^2}} \quad (24)$$

by defining

$$L \equiv \frac{K}{\sqrt{1 + K^2}}, \quad (25)$$

so

$$\sin\theta = \sqrt{\frac{1 - L}{2}} \quad (26)$$

$$\cos\theta = \sqrt{\frac{1 + L}{2}}. \quad (27)$$

Rotating by an angle

$$\theta = \tfrac{1}{2} \cot^{-1}\left(\frac{c - a}{2b}\right) \quad (28)$$

therefore transforms (1) into

$$a'x'^2 + c'y'^2 + 2d'x' + 2f'y' + g' = 0. \quad (29)$$

COMPLETING THE SQUARE,

$$a'\left(x'^2 + \frac{2d'}{a'}x\right) + c'\left(y'^2 + \frac{2f'}{c'}y'\right) + g' = 0 \quad (30)$$

$$a'\left(x' \frac{d'}{a'}\right)^2 + c'\left(y' + \frac{f'}{c'}\right)^2 = -g' + \frac{d'^2}{a'} + \frac{f'^2}{c'}. \quad (31)$$

Defining $x'' \equiv x' + d'/a'$, $y'' \equiv y' + f'/c'$, and $g'' \equiv -g' + d'^2/a' + f'^2/c'$ gives

$$a'x'^2 + c'y''^2 = g''. \quad (32)$$

If $g'' \neq 0$, then divide both sides by g''. Defining $a'' \equiv a'/g''$ and $c'' \equiv c'/g''$ then gives

$$a''x''^2 + c''y''^2 = 1. \quad (33)$$

Therefore, in an appropriate coordinate system, the general CONIC SECTION can be written (dropping the primes) as

$$\begin{cases} ax^2 + cy^2 = 1 & a, c, g \neq 0 \\ ax^2 + cy^2 = 0 & a, c \neq 0, g = 0. \end{cases} \quad (34)$$

Consider an equation OF THE FORM $ax^2 + 2bxy + cy^2 = 1$ where $b \neq 0$. Re-express this using t_1 and t_2 in the form

$$ax^2 + 2bxy + cy^2 = t_1x'^2 + t_2y'^2. \quad (35)$$

Therefore, rotate the COORDINATE SYSTEM

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}, \quad (36)$$

so

$$ax^2 + 2bxy + cy^2 = t_1x'^2 + t_2y'^2$$

$$= t_1\left(x^2 \cos^2\theta + 2xy \cos\theta \sin\theta + y^2 \sin^2\theta\right)$$

$$+t_2\left(x^2 \sin^2\theta - 2xy \sin\theta \cos\theta + y^2 \cos^2\theta\right)$$

$$= x^2(t_1 \cos^2\theta + t_2 \sin^2\theta) + 2xy \cos\theta \sin\theta (t_1 - t_2)$$
$$+ y^2(t_1 \sin^2\theta + t_2 \cos^2\theta) \quad (37)$$

and

$$a = t_1 \cos^2\theta + t_2 \sin^2\theta \quad (38)$$

$$b = (t_1 - t_2)\cos\theta \sin\theta = \tfrac{1}{2}(t_1 - t_2)\sin(2\theta) \quad (39)$$

$$c = t_1 \sin^2\theta + t_2 \cos^2\theta. \quad (40)$$

Therefore,

$$a + c = (t_1 \cos^2\theta + t_2 \sin^2\theta) + (t_1 \sin^2\theta + t_2 \cos^2\theta)$$
$$= t_1 + t_2 \quad (41)$$

$$a - c = t_1 \cos^2\theta + t_2 \sin^2\theta - t_1 \sin^2\theta + t_2 \cos^2\theta$$
$$= (t_1 - t_2)(\cos^2\theta - \sin^2\theta) = (t_1 - t_2)\cos(2\theta). \quad (42)$$

From (41) and (42),

$$\frac{a-c}{b} = \frac{(t_1 - t_2)\cos(2\theta)}{\frac{1}{2}(t_1 - t_2)\sin(2\theta)} = 2\cot(2\theta), \quad (43)$$

the same angle as before. But

$$\cos(2\theta) = \cos\left[\cot^{-1}\left(\frac{a-c}{2b}\right)\right]$$
$$= \cos\left[\tan^{-1}\left(\frac{2b}{a-c}\right)\right]$$
$$= \frac{1}{\sqrt{1 + \left(\frac{2b}{a-c}\right)^2}}, \quad (44)$$

so

$$a - c = \frac{t_1 - t_2}{\sqrt{1 + \left(\frac{2b}{a-c}\right)^2}}. \quad (45)$$

Rewriting and copying (41),

$$t_1 - t_2 = (a - c)\sqrt{1 + \left(\frac{2b}{a-c}\right)^2}$$
$$= \sqrt{(a-c)^2 + 4b^2} \quad (46)$$

$$t_1 + t_2 = a + c. \quad (47)$$

Adding (46) and (47) gives

$$t_1 = \tfrac{1}{2}\left[a + c + \sqrt{(a-c)^2 + 4b^2}\right] \quad (48)$$

$$t_2 = a + c - t_1 = \tfrac{1}{2}\left[a + c - \sqrt{(a-c)^2 + 4b^2}\right]. \quad (49)$$

Note that these ROOTS can also be found from

$$(t - t_1)(t - t_2) = t^2 - t(t_1 + t_2) + t_1 t_2 = 0 \quad (50)$$

$$t_2 - t(a+c) + \tfrac{1}{4}\left\{(a+c)^2 - \left[(a-c)^2 + 4b^2\right]\right\}$$
$$= t_2 - t(a+c) + \tfrac{1}{4}\left[a^2 + 2ac + c^2 - a^2 + 2ac - c^2 - 4b^2\right]$$
$$= t^2 - t(a+c) + (ac - b^2) = (a-t)(c-t) - b^2$$
$$= \begin{vmatrix} a-t & b \\ b & c-t \end{vmatrix} = (a-t)(c-t) - b^2 = 0. \quad (51)$$

The original problem is therefore equivalent to looking for a solution to

$$\begin{bmatrix} a & b \\ b & c \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = t\begin{bmatrix} x \\ y \end{bmatrix} \quad (52)$$

$$\begin{bmatrix} ax & bx \\ by & cy \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = t\begin{bmatrix} x^2 \\ y^2 \end{bmatrix}, \quad (53)$$

which gives the simultaneous equations

$$\begin{cases} ax^2 + bxy = tx^2 \\ bxy + cy^2 = ty^2. \end{cases} \quad (54)$$

Let $\mathbf{X}$ be any point (x, y) with old coordinates and (x', y') be its new coordinates. Then

$$ax^2 + 2bxy + cy^2 = t_+ x'^2 + t_- y'^2 = 1 \quad (55)$$

and

$$x' = \hat{\mathrm{X}}_+ \cdot \begin{bmatrix} x \\ y \end{bmatrix} \quad (56)$$

$$y' = \hat{\mathrm{X}}_- \cdot \begin{bmatrix} x \\ y \end{bmatrix}. \quad (57)$$

If t_+ and t_- are both > 0, the curve is an ELLIPSE. If t_+ and t_- are both < 0, the curve is empty. If t_+ and t_- have opposite SIGNS, the curve is a HYPERBOLA. If either is 0, the curve is a PARABOLA. To find the general form of a quadratic curve in POLAR COORDINATES (as given, for example, in Moulton 1970), plug $x = r\cos\theta$ and $y = r\sin\theta$ into (1) to obtain

$$ar^2\cos^2\theta + 2br^2\cos\theta\sin\theta + cr^2\sin^2\theta + 2dr\cos\theta$$
$$+ 2fr\sin\theta + g = 0 \quad (58)$$

$$(a\cos^2\theta + 2b\cos\theta\sin\theta + c\sin^2\theta) + \frac{2}{r}$$
$$\times (d\cos\theta + f\sin\theta) + \frac{g}{r^2} = 0. \quad (59)$$

Define $u \equiv 1/r$. For $g \neq 0$, we can divide through by $2g$,

$$\frac{1}{2}u^2+\frac{1}{g}(d\cos\theta+f\sin\theta)u+\frac{1}{2g}$$
$$\times(a\cos^2\theta+2b\cos\theta\sin\theta+c\sin^2\theta)=0. \tag{60}$$

Applying the QUADRATIC FORMULA gives

$$u=-\frac{d}{g}\cos\theta-\frac{f}{g}\sin\theta\pm\sqrt{R}, \tag{61}$$

where

$$R\equiv\frac{(d\cos\theta+f\sin\theta)^2}{g^2}$$
$$-4\left(\frac{1}{2}\right)\left(\frac{1}{2g}\right)(a\cos^2\theta+2b\cos\theta\sin\theta+c\sin^2\theta)$$
$$=\frac{d^2}{g^2}\cos^2\theta+\frac{2df}{g^2}\cos\theta\sin\theta+\frac{f^2}{g^2}\sin^2\theta$$
$$-\frac{1}{g}(a\cos^2\theta+2b\cos\theta\sin\theta+c\sin^2\theta). \tag{62}$$

Using the trigonometric identities

$$\sin^2\theta=1-\cos^2\theta \tag{63}$$
$$\sin(2\theta)=2\sin\theta\cos\theta, \tag{64}$$

it follows that

$$R=\left(\frac{d^2}{g^2}-\frac{a}{g}-\frac{f^2}{g^2}+\frac{c}{g}\right)\cos^2\theta+\left(\frac{df}{g^2}-\frac{b}{g}\right)\sin(2\theta)$$
$$+\left(\frac{f^2}{g^2}-\frac{c}{g}\right)$$
$$=\tfrac{1}{2}[1+\cos(2\theta)]\frac{d^2-ag-f^2+cg}{g^2}+\sin(2\theta)$$
$$\times\left(\frac{df-bg}{g^2}\right)+\frac{f^2-cg}{g^2}\frac{d^2-ag-f^2+cg}{2g^2}\cos(2\theta)$$
$$+\frac{df-db}{g^2}\sin(2\theta)$$
$$+\frac{d^2-ag-f^2+cg+2f^2-2cg}{2g^2}. \tag{65}$$

Defining

$$A\equiv-\frac{f}{g} \tag{66}$$
$$B\equiv-\frac{d}{g} \tag{67}$$
$$C\equiv\frac{df-bg}{g^2} \tag{68}$$
$$D\equiv\frac{d^2-f^2+cg-ag}{2g^2} \tag{69}$$
$$E\equiv\frac{d^2+f^2-ag-cg}{2g^2} \tag{70}$$

then gives the equation

$$u\equiv\frac{1}{r}$$
$$=A\sin\theta+B\cos\theta\pm\sqrt{C\sin(2\theta)+D\cos(2\theta)+E} \tag{71}$$

(Moulton 1970). If $g=0$, then (0) becomes instead

$$u\equiv\frac{1}{r}=-\frac{a\cos^2\theta+2b\cos\theta\sin\theta+c\sin^2\theta}{2(d\cos\theta+f\sin\theta)}. \tag{72}$$

Therefore, the general form of a quadratic curve in polar coordinates is given by

$$u=\begin{cases}\begin{array}{c}A\sin\theta+B\cos\theta\\ \pm\sqrt{C\sin(2\theta)+D\cos(2\theta)+E}\end{array} & \text{for } g\neq 0\\ -\dfrac{a\cos^2\theta+2b\cos\theta\sin\theta+c\sin^2\theta}{2(d\cos\theta+f\sin\theta} & \text{for } g=0.\end{cases} \tag{73}$$

Quadratic Effect

PRIME QUADRATIC EFFECT

Quadratic Equation

A quadratic equation is a second-order POLYNOMIAL

$$ax^2+bx+c=0, \tag{1}$$

with $a\neq 0$. The roots x can be found by COMPLETING THE SQUARE:

$$x^2+\frac{b}{a}x=-\frac{c}{a} \tag{2}$$

$$\left(x+\frac{b}{2a}\right)^2=-\frac{c}{a}+\frac{b^2}{4a^2}=\frac{b^2-4ac}{4a^2} \tag{3}$$

$$x + \frac{b}{2a} = \frac{\pm\sqrt{b^2 - 4ac}}{2a}. \quad (4)$$

Solving for x then gives

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}. \quad (5)$$

This is the QUADRATIC FORMULA.

An alternate form is given by dividing (1) through by x^2:

$$a + \frac{b}{x} + \frac{c}{x^2} = 0 \quad (6)$$

$$c\left(\frac{1}{x^2} + \frac{b}{cx}\right) + a = 0 \quad (7)$$

$$c\left(\frac{1}{x} + \frac{b}{2c}\right)^2 = c\left(\frac{b}{2c}\right)^2 - a = \frac{b^2}{4c} - \frac{4ac}{4c} = \frac{b^2 - 4ac}{4c}. \quad (8)$$

Therefore,

$$\frac{1}{x} + \frac{b}{2c} = \pm\frac{\sqrt{b^2 - 4ac}}{2c} \quad (9)$$

$$\frac{1}{x} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2c} \quad (10)$$

$$x = \frac{2c}{-b \pm \sqrt{b^2 - 4ac}}. \quad (11)$$

This form is helpful if $b^2 \gg 4ac$, in which case the usual form of the QUADRATIC FORMULA can give inaccurate numerical results for one of the ROOTS. This can be avoided by defining

$$q \equiv -\tfrac{1}{2}\left[b + \operatorname{sgn}(b)\sqrt{b^2 - 4ac}\right] \quad (12)$$

so that b and the term under the SQUARE ROOT sign always have the same sign. Now, if $b > 0$, then

$$q = -\tfrac{1}{2}\left(b + \sqrt{b^2 - 4ac}\right) \quad (13)$$

$$\frac{1}{q} = \frac{-2}{b + \sqrt{b^2 - 4ac}}\,\frac{b - \sqrt{b^2 - 4ac}}{b - \sqrt{b^2 - 4ac}}$$

$$= \frac{-2\left(b - \sqrt{b^2 - 4ac}\right)}{b^2 - (b^2 - 4ac)}$$

$$= \frac{-2\left(b - \sqrt{b^2 - 4ac}\right)}{4ac} = \frac{-b + \sqrt{b^2 - 4ac}}{2ac}, \quad (14)$$

so

$$x_1 \equiv \frac{q}{a} = \frac{-b - \sqrt{b^2 - 4ac}}{2a} \quad (15)$$

$$x_2 \equiv \frac{c}{q} = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad (16)$$

Similarly, if $b < 0$, then

$$q = -\tfrac{1}{2}\left(b - \sqrt{b^2 - 4ac}\right) = \tfrac{1}{2}\left(-b + \sqrt{b^2 - 4ac}\right) \quad (17)$$

$$\frac{1}{q} = \frac{-2}{-b + \sqrt{b^2 - 4ac}}\,\frac{b + \sqrt{b^2 - 4ac}}{b + \sqrt{b^2 - 4ac}}$$

$$= \frac{2\left(b + \sqrt{b^2 - 4ac}\right)}{-b^2 + (b^2 - 4ac)}$$

$$= \frac{b + \sqrt{b^2 - 4ac}}{-2ac} = \frac{-b - \sqrt{b^2 - 4ac}}{2ac}, \quad (18)$$

so

$$x_1 \equiv \frac{q}{a} = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad (19)$$

$$x_2 \equiv \frac{c}{q} = \frac{-b - \sqrt{b^2 - 4ac}}{2a} \quad (20)$$

Therefore, the ROOTS are always given by $x_1 = q/a$ and $x_2 = c/q$.

Now consider the equation expressed in the form

$$a_2x^2 + a_1x + a_0 = 0, \quad (21)$$

with solutions z_1 and z_2. These solutions satisfy NEWTON'S RELATIONS

$$z_1 + z_2 = -\frac{a_1}{a_2} \quad (22)$$

$$z_1z_2 = \frac{a_0}{a_2}. \quad (23)$$

The properties of the SYMMETRIC POLYNOMIALS appearing in NEWTON'S RELATIONS then give

$$z_1^2 + z_2^2 = \frac{a_1^2 - 2a_0a_2}{a_2^2} \quad (24)$$

$$z_1^3 + z_2^3 = -\frac{a_1^3 - 3a_0a_1a_2}{a_2^3} \quad (25)$$

$$z_1^4 + z_2^4 = \frac{a_1^4 - 4a_0a_1^2a_2 + 2a_0^2a_2^2}{a_2^4}. \quad (26)$$

Quadratic Field

An ALGEBRAIC INTEGER OF THE FORM $a+b\sqrt{D}$ where D is SQUAREFREE forms a quadratic field and is denoted $\mathbb{Q}(\sqrt{D})$. If $D>0$, the field is called a REAL QUADRATIC FIELD, and if $D<0$, it is called an IMAGINARY QUADRATIC FIELD. The integers in $\mathbb{Q}(\sqrt{1})$ are simply called "the" INTEGERS. The integers in $\mathbb{Q}(\sqrt{-1})$ are called GAUSSIAN INTEGERS, and the integers in $\mathbb{Q}(\sqrt{-3})$ are called EISENSTEIN INTEGERS. The ALGEBRAIC INTEGERS in an arbitrary quadratic field do not necessarily have unique factorizations. For example, the fields $\mathbb{Q}(\sqrt{-5})$ and $\mathbb{Q}(\sqrt{-6})$ are not uniquely factorable, since

$$21=3\cdot 7=\left(1+2\sqrt{-5}\right)\left(1-2\sqrt{-5}\right) \tag{1}$$

$$6=-\sqrt{6}\left(\sqrt{-6}\right)=2\cdot 3, \tag{2}$$

although the above factors are all primes within these fields. All other quadratic fields $\mathbb{Q}\left(\sqrt{D}\right)$ with $|D|\le 7$ *are* uniquely factorable.

Quadratic fields obey the identities

$$\left(a+b\sqrt{D}\right)\pm\left(c+d\sqrt{D}\right)=(a\pm c)+(b\pm d)\sqrt{D}, \tag{3}$$

$$\left(a+b\sqrt{D}\right)\left(c+d\sqrt{D}\right)=(ac+bdD)+(ad+bc)\sqrt{D}, \tag{4}$$

and

$$\frac{a+b\sqrt{D}}{c+d\sqrt{D}}=\frac{ac-bdD}{c^2-d^2D}+\frac{(bc-ad)}{c^2-d^2D}\sqrt{D} \tag{5}$$

The INTEGERS in the real field $\mathbb{Q}\left(\sqrt{D}\right)$ are of the form $r+sp$, where

$$\rho=\begin{cases}\sqrt{D} & \text{for } D\equiv 2 \textit{ or } D\equiv 3 \pmod 4\\ \frac{1}{2}\left(-1+\sqrt{D}\right) & \text{for } D\equiv 1 \pmod 4.\end{cases} \tag{6}$$

There are exactly 21 quadratic fields in which there is a EUCLIDEAN ALGORITHM, corresponding to $\mathbb{Q}(m)$ for SQUAREFREE integers -11, -7, -3, -2, -1, 2, 3, 5, 6, 7, 11, 13, 17, 19, 21, 29, 33, 37, 41, 57, and 73 (Sloane, N. J. A. Sequences048981). This list was published by Inkeri (1947), but erroneously included the spurious additional term 97 (Barnes and Swinnerton-Dyer 1952; Hardy and Wright 1979, p. 217).

Quadratic Form

A quadratic form involving n REAL variables $x_1, x_2, \ldots, x_n$ associated with the $n\times n$ MATRIX $\mathsf{A}=a_{ij}$ is given by

$$Q(x_1,x_2,\ldots x_n)=a_{ij}x_ix_j, \tag{1}$$

where EINSTEIN SUMMATION has been used. Letting $\mathbf{x}$ be a VECTOR made up of x_1, ..., x_n and $\mathbf{x}^{\mathrm{T}}$ the TRANSPOSE, then

$$Q(\mathbf{x})=\mathbf{x}^{\mathrm{T}}\mathsf{A}\mathbf{x}, \tag{2}$$

equivalent to

$$Q(\mathbf{x})=(\mathbf{x},\mathsf{A}\mathbf{x}) \tag{3}$$

in INNER PRODUCT notation. A BINARY QUADRATIC

FORM is a quadratic form in two variables and has the form

$$Q(x, y) = a_{11}x^2 + 2a_{12}xy + a_{22}y^2. \quad (4)$$

It is always possible to express an arbitrary quadratic form

$$Q(\mathbf{x}) = a_{ij}x_i x_j, \quad (5)$$

in the form

$$Q(\mathbf{x}) = (\mathbf{x}, \mathsf{A}\mathbf{x}), \quad (6)$$

where $\mathsf{A} = a_{ii}$ is a SYMMETRIC MATRIX given by

$$a_{ij} = \begin{cases} a_{ii} & i = j \\ \frac{1}{2}(a_{ij} + a_{ji}) & i \neq j. \end{cases} \quad (7)$$

Any REAL quadratic form in n variables may be reduced to the diagonal form

$$Q(x) = \lambda_1 x_1^2 + \lambda_2 x_2^2 + \ldots + \lambda_n x_n^2 \quad (8)$$

with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$ by a suitable orthogonal point-transformation. Also, two real quadratic forms are equivalent under the group of linear transformations IFF they have the same RANK and SIGNATURE.

Quadratic Formula

The formula giving the ROOTS of a QUADRATIC EQUATION

$$ax^2 + bx + c = 0 \quad (1)$$

as

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}. \quad (2)$$

An alternate form is given by

$$x = \frac{2c}{-b \pm \sqrt{b^2 - 4ac}}. \quad (3)$$

See also QUADRATIC EQUATION

Quadratic Integral

To compute an integral OF THE FORM

$$\int \frac{dx}{a + bx + cx^2}, \quad (1)$$

COMPLETE THE SQUARE in the DENOMINATOR to obtain

$$\int \frac{dx}{a + bx + cx^2} = \frac{1}{c} \int \frac{dx}{\left(x + \frac{b}{2c}\right)^2 + \left(\frac{a}{c} - \frac{b^2}{4c^2}\right)}. \quad (2)$$

Let $u \equiv x + b/2c$. Then define

$$-A^2 \equiv \frac{a}{c} - \frac{b^2}{4c^2} = \frac{1}{4c^2}(4ac - b^2) \equiv \frac{1}{4c^2} q, \quad (3)$$

where

$$q \equiv 4ac - b^2 \quad (4)$$

is the NEGATIVE of the DISCRIMINANT. If $q < 0$, then

$$A = \frac{1}{2c}\sqrt{-q}. \quad (5)$$

Now use PARTIAL FRACTION DECOMPOSITION,

$$\frac{1}{c} \int \frac{du}{(u + A)(u - A)} = \frac{1}{c} \int \left(\frac{A_1}{u + A} + \frac{A_2}{u - A}\right) du \quad (6)$$

$$\left(\frac{A_1}{u + A} + \frac{A_2}{u - A}\right) = \frac{A_1(u - A) + A_2(u + A)}{u^2 - A^2}$$

$$= \frac{(A_1 + A_2)u + A(A_2 - A_1)}{u^2 - A^2}, \quad (7)$$

so $A_2 + A_1 = 0 \Rightarrow A_2 = -A_1$ and $A(A_2 - A_1) = -2AA_1 = 1 \Rightarrow A_1 = -1/(2A)$. Plugging these in,

$$\frac{1}{c} \int \left(-\frac{1}{2A}\frac{1}{u + A} + \frac{1}{2A}\frac{1}{u - A}\right) du$$

$$= \frac{1}{2Ac}[-\text{In}(u + A) + \text{In}(u - A)]$$

$$= \frac{1}{2Ac} In\left(\frac{u - A}{u + A}\right)$$

$$= \frac{1}{2\left(\frac{1}{2c}\right)\sqrt{-qc}} \ln\left(\frac{x+\frac{b}{2c}-\frac{1}{2c}\sqrt{-q}}{x+\frac{b}{2c}+\frac{1}{2c}\sqrt{-q}}\right)$$

$$= \frac{1}{\sqrt{-q}} In\left(\frac{2cx+b-\sqrt{-q}}{2cx+b+\sqrt{-q}}\right) \quad (8)$$

for $q < 0$. Note that this integral is also tabulated in Gradshteyn and Ryzhik (2000, equation 2.172), where it is given with a sign flipped.

Quadratic Invariant

Given the BINARY QUADRATIC FORM

$$ax^2 + 2bxy + cy^2 \quad (1)$$

with DISCRIMINANT $b^2 - ac$, let

$$x = pX + qY \quad (2)$$

$$y = rX + sY\cdot \quad (3)$$

Then

$$a(pX+qY)^2 + 2b(pX+qY)(rX+sY) + c(rX+sY)^2$$

$$= AX^2 + 2BXY + CY^2, \quad (4)$$

where

$$A = ap^2 + 2bpr + cr^2 \quad (5)$$

$$B = apq + b(ps+qr) + crs \quad (6)$$

$$C = aq^2 + 2bqs + cs^2, \quad (7)$$

so

$$B^2 - AC = \left[a^2p^2q^2 + b^2(ps+qr)^2 + c^2r^2s^2\right.$$

$$\left.+2abpq(ps+qr) + 2acpqrs + 2bcrs(ps+qr)\right]$$

$$-\left(ap^2+2bpr+cr^2\right)\left(aq^2+2bqs+cs^2\right)$$

$$= a^2p^2q^2 + b^2p^2s^2 + 2b^2pqrs + b^2q^2r^2 + c^2r^2s^2$$

$$+2abp^2qs + 2abpq^2r + 2acpqrs + 2bcprs^2 + 2bcqr^2s$$

$$-a^2p^2q^2 - 2abp^2qs - acp^2s^2 - 2abpq^2r - 4b^2pqrs$$

$$-2bcprs^2 - acq^2r^2 - 2bcqr^2s - c^2r^2s^2$$

$$= b^2p^2s^2 - 2b^2pqrs + b^2q^2r^2 + 2acprs - acp^2s^2$$

$$-acp^2r^2$$

$$= p^2s^2\left(b^2-ac\right) + q^2r^2\left(b^2-ac\right) - 2pqrs\left(b^2-ac\right)$$

$$= \left(b^2-ac\right)\left(p^2s^2 - 2pqrs + q^2r^2\right)$$

$$= (ps-rq)^2\left(b^2-ac\right)\cdot \quad (8)$$

Surprisingly, this is the same discriminant as before, but multiplied by the factor $(ps-rq)^2$. The quantity $ps-rq$ is called the MODULUS.

See also ALGEBRAIC INVARIANT

Quadratic Irrational Number

An IRRATIONAL NUMBER OF THE FORM

$$\frac{P \pm \sqrt{D}}{Q},$$

where P and Q are INTEGERS and D is a SQUAREFREE INTEGER. Quadratic irrational numbers are sometimes also called quadratic surds. In 1770, Lagrange proved that any quadratic irrational has a CONTINUED FRACTION which is periodic after some point.

See also CONTINUED FRACTION, MINKOWSKI'S QUESTION MARK FUNCTION

Quadratic Map

A 1-D MAP often called "the" quadratic map is defined by

$$x_{n+1} = x_n^2 + c\cdot \quad (1)$$

This is the real version of the complex map defining the MANDELBROT SET. The quadratic map is called attracting if the JACOBIAN $J < 1$, and repelling if $J > 1$. FIXED POINTS occur when

$$x^{(1)} = [x^{(1)}]^2 + c \quad (2)$$

$$\left(x^{(1)}\right)^2 - x^{(1)} + c = 0 \quad (3)$$

$$x_\pm^{(1)} = \tfrac{1}{2}\left(1 \pm \sqrt{1-4c}\right). \quad (4)$$

Period two FIXED POINTS occur when

$$x_{n+2} = x_{n+1}^2 + c = \left(x_n^2 + c\right)^2 + c$$

$$= x_n^4 + 2cx_n^2 + (c^2+c) = x_n \quad (5)$$

$$x^4 + 2x^2 - x + \left(cx^2 + c\right) = \left(x^2 - x + c\right)\left(x^2 + x + 1 + c\right)$$

$$= 0 \quad (6)$$

$$x_\pm^{(2)} = \tfrac{1}{2}\left[1 \pm \sqrt{1-4(1+c)}\right] = \tfrac{1}{2}\left(1 \pm \sqrt{-3-4c}\right). \quad (7)$$

Period three FIXED POINTS occur when

$$x^6 + x^5 + (3c+1)x^4 + (2c+1)x^3 + (c^2+3c+1)x^2$$

$$+(c+1)^2x + \left(c^3 + 2c^2 + c + 1\right) = 0\cdot \quad (8)$$

The most general second-order 2-D MAP with an elliptic fixed point at the origin has the form

$$x' = x \cos\alpha - y \sin\alpha + a_{20}x^2 + a_{11}xy + a_{02}y^2 \quad (9)$$

$$y' = x \sin\alpha + y \cos\alpha + b_{20}x^2 + b_{11}xy + b_{02}y^2. \quad (10)$$

The map must have a DETERMINANT of 1 in order to be AREA-preserving, reducing the number of independent parameters from seven to three. The map can then be put in a standard form by scaling and rotating to obtain

$$x' = x \cos\alpha - y \sin\alpha + x^2 \sin\alpha \quad (11)$$

$$y' = x \sin\alpha + y \cos\alpha - x^2 \cos\alpha. \quad (12)$$

The inverse map is

$$x = x' \cos\alpha + y' \sin\alpha \quad (13)$$

$$y = -x' \sin\alpha + y' \cos\alpha + (x' \cos\alpha + y' \sin\alpha)^2. \quad (14)$$

The FIXED POINTS are given by

$$x_i^2 \sin\alpha + 2x_i \cos\alpha - x_{i-1} - x_{i+1} = 0 \quad (15)$$

for $i = 0, \ldots, n-1$.

See also BOGDANOV MAP, HÉNON MAP, LOGISTIC MAP, LOZI MAP, MANDELBROT SET

Quadratic Mean

ROOT-MEAN-SQUARE

Quadratic Nonresidue

QUADRATIC RESIDUE

Quadratic Phase Array

A method to obtain a signal $C_\ell(z)$ with a flat spectrum $c(\theta; z)$ (such as a pulse), but having a smaller amplitude than the pulse.

$$c(\theta, z) \equiv e^{iz\phi(\theta)} = \sum_{\ell=-\infty}^{\infty} e^{i\ell\theta} C\ell(z), \quad (1)$$

whence

$$C_\ell(z) = 1/(2\pi) \int_{-\pi}^{\pi} e^{i(z\phi(\theta) - \ell\theta)} d\theta, \quad (2)$$

where

$$\phi(\theta) = (1 - |\theta|/\pi)\theta/\pi, \quad (3)$$

with $|\theta| \leq \pi$.

Thus $c(\theta; z)$ and $C_\ell(z)$ are a Fourier pair, and since $|c(\theta, z)| = 1$, it is guaranteed that the sequence C_ℓ has a flat spectrum. The sequence C_ℓ is called the "quadratic phase array."

Quadratic Reciprocity Law

QUADRATIC RECIPROCITY THEOREM

Quadratic Reciprocity Theorem

Also called the AUREUM THEOREMA (GOLDEN THEOREM) by Gauss. If p and q are distinct ODD PRIMES, then the CONGRUENCES

$$x^2 \equiv q \pmod{p}$$

$$x^2 \equiv p \pmod{q}$$

are both solvable or both unsolvable unless both p and q leave the remainder 3 when divided by 4 (in which case one of the CONGRUENCES is solvable and the other is not). Written symbolically,

$$\left(\frac{p}{q}\right)\left(\frac{q}{p}\right) = (-1)^{(p-1)(q-1)/4},$$

where

$$\left(\frac{p}{q}\right) \equiv \begin{cases} 1 & \text{for } x^2 \equiv p \pmod{q} \text{ solvable for } x \\ -1 & \text{for } x^2 \equiv p \pmod{q} \text{ not solvable for } x \end{cases}$$

is known as a LEGENDRE SYMBOL.

Euler stated the theorem in 1783 without proof. Legendre was the first to publish a proof, but it was fallacious. In 1796, Gauss became the first to publish a correct proof (Nagell 1951, p. 144). The quadratic reciprocity theorem was Gauss's favorite theorem from NUMBER THEORY, and he devised no fewer than eight different proofs of it over his lifetime.

The GENUS THEOREM states that the DIOPHANTINE EQUATION

$$x^2 + y^2 = p$$

can be solved for p a PRIME IFF $p \equiv 1 \pmod{4}$ or $p = 2$.

See also GENUS THEOREM, JACOBI SYMBOL, KRONECKER SYMBOL, LEGENDRE SYMBOL, QUADRATIC RESIDUE, RECIPROCITY THEOREM

Quadratic Recurrence

N.B. A detailed online essay by S. Finch was the starting point for this entry.

A quadratic recurrence is a RECURRENCE RELATION on a SEQUENCE of numbers $\{x_n\}$ expressing x_n as a second degree polynomial in x_k with $k<n$. For example,

$$x_n = x_{n-1}x_{n-2} \tag{1}$$

is a quadratic recurrence. Another simple example is

$$x_n = (x_{n-1})^2 \tag{2}$$

with $x_0 = 2$, which has solution $x_n = 2^{2^n}$. Another example is the number of "strongly" binary trees of height $\leq n$, given by

$$y_n = (y_{n-1})^2 + 1 \tag{3}$$

with $y_0 = 1$. This has solution

$$y_n = \lfloor c^{2^n} \rfloor, \tag{4}$$

where

$$c = \exp\left[\sum_{j=0}^{\infty} 2^{-j-1} \ln\left(1 + y_j^{-2}\right)\right] = 1.502836801\ldots \tag{5}$$

and $\lfloor x \rfloor$ is the FLOOR FUNCTION (Aho and Sloane 1973). A third example is the closest strict under-approximation of the number 1,

$$s_n = \sum_{i=1}^{n} \frac{1}{z_i}, \tag{6}$$

where $1 < z_1 < \ldots < z_n$ are integers. The solution is given by the recurrence

$$z_n = (z_{n-1})^2 - z_{n-1} + 1, \tag{7}$$

with $z_1 = 2$. This has a closed solution as

$$z_n = \left\lfloor d^{2^n} + \tfrac{1}{2} \right\rfloor \tag{8}$$

where

$$d = \tfrac{1}{2}\sqrt{6}\exp\left\{\sum_{j=1}^{\infty} 2^{-j-1} \ln\left[1 + (2z_j - 1)^{-2}\right]\right\} = 1.2640847353\ldots \tag{9}$$

(Aho and Sloane 1973). A final example is the well-known recurrence

$$c_n = (c_{n-1})^2 - \mu \tag{10}$$

with $c_0 = 0$ used to generate the MANDELBROT SET.

Quadratic Representation

SUM OF SQUARES FUNCTION

Quadratic Residue

If there is an INTEGER x such that

$$x^2 \equiv q \pmod{p}, \tag{1}$$

then q is said to be a quadratic residue (mod p). If not, q is said to be a quadratic nonresidue (mod p). Hardy and Wright (1979, pp. 67–68) use the shorthand notations $q \mathrm{R} p$ and $q \mathrm{N} p$, to indicated that q is a quadratic residue or nonresidue, respectively.

For example, $4^2 \equiv 6$, so 6 is a quadratic residue (mod 10). The entire set of quadratic residues (mod 10) are given by 1, 4, 5, 6, and 9, since

$$1^2 \equiv 1 \pmod{10} \quad 2^2 \equiv 4 \pmod{10} \quad 3^2 \equiv 9 \pmod{10}$$
$$4^2 \equiv 6 \pmod{10} \quad 5^2 \equiv 5 \pmod{10} \quad 6^2 \equiv 6 \pmod{10}$$
$$7^2 \equiv 9 \pmod{10} \quad 8^2 \equiv 4 \pmod{10} \quad 9^2 \equiv 1 \pmod{10}$$

making the numbers 2, 3, 7, and 8 the quadratic nonresidues (mod 10).

A list of quadratic residues for $p \leq 29$ is given below (Sloane's A046071), with those numbers $< p$ not in the list being quadratic nonresidues of p.

p	Quadratic Residues
1	(none)
2	1
3	1
4	1
5	1, 4
6	1, 3, 4
7	1, 2, 4
8	1, 4
9	1, 4, 7
10	1, 4, 5, 6, 9
11	1, 3, 4, 5, 9
12	1, 4, 9
13	1, 3, 4, 9, 10, 12
14	1, 2, 4, 7, 8, 9, 11
15	1, 4, 6, 9, 10
16	1, 4, 9

17	1, 2, 4, 8, 9, 13, 15, 16
18	1, 4, 7, 9, 10, 13, 16
19	1, 4, 5, 6, 7, 9, 11, 16, 17
20	1, 4, 5, 9, 16

Given an ODD PRIME p and an INTEGER a, then the LEGENDRE SYMBOL is given by

$$\left(\frac{a}{p}\right) = \begin{cases} 1 & \text{if a is a quadratic residue mod } p \\ -1 & \text{otherwise.} \end{cases} \qquad (2)$$

If

$$r^{(p-1)/2} \equiv \pm 1 \pmod{p}, \qquad (3)$$

then r is a quadratic residue (+) or nonresidue (–). This can be seen since if r is a quadratic residue of p, then there exists a square x^2 such that $r \equiv x^2 \pmod{p}$, so

$$r^{(p-1)/2} \equiv \left(x^2\right)^{(p-1)/2} \equiv x^{p-1} \pmod{p}, \qquad (4)$$

and x^{p-1} is congruent to 1 (mod p) by FERMAT'S LITTLE THEOREM.

Given p and q in the congruence

$$x^2 \equiv q \pmod{p}, \qquad (5)$$

x can be explicitly computed for p and q of certain special forms:

$$x = \begin{cases} q^{k+1} \pmod{p} \\ \quad \text{for } p = 4k+3 \\ q^{k+1} \pmod{p} \\ \quad \text{for } p = 8k+5 \text{ and } q^{2k+1} \equiv 1 \pmod{p} \\ \frac{1}{2}(4q)^{k+1}(p+1) \pmod{p} \\ \quad \text{for } p = 8k+5 \text{ and } q^{2k+1} \equiv -1 \pmod{p}. \end{cases} \qquad (6)$$

For example, the first form can be used to find x given the quadratic residues $q = 1$, 3, 4, 5, and 9 (mod $p = 11$, having $k = 2$), whereas the second and third forms determine x given the quadratic residues $q = 1$, 3, 4, 9, 10, and 12 (mod $p = 13$, having $k = 1$), and $q = 1, 3, 4, 7, 9, 10, 11, 12, 16, 21, 25, 26, 27, 28, 30, 33, 34, 36$ (mod $p = 37$, having $k = 4$).

More generally, let q be a quadratic residue modulo an ODD PRIME p. Choose h such that the LEGENDRE SYMBOL $(h^2 - 4q/p) = -1$. Then defining

$$V_1 = h \qquad (7)$$

$$V_2 = h^2 - 2q \qquad (8)$$

$$V_i = hV_{i-1} - qV_{i-2} \quad \text{for } i \geq 3, \qquad (9)$$

gives

$$V_{2i} = V_i^2 - 2q^i \qquad (10)$$

$$V_{2i+1} = V_i V_{i+1} - hn^i, \qquad (11)$$

and a solution to the quadratic CONGRUENCE is

$$x = \tfrac{1}{2}(p+1)V_{(p+1)/2} \pmod{p}. \qquad (12)$$

Schoof (1985) gives an algorithm for finding x with running time $\mathcal{O}(\ln n)^{10}$ (Hardy *et al.* 1990). The congruence is solved by the *Mathematica* command `SqrtMod[q, p]` in the *Mathematica* add-on package `NumberTheory`NumberTheoryFunctions`` (which can be loaded with the command `<< NumberTheory``).

The following table gives the PRIMES which have a given number d as a quadratic residue.

d	Primes
-6	24k + 1,5,7,11
-5	20k + 1,3,7,9
-3	6k + 1
-2	8k + 1,3
-1	4k + 1
2	8k ± 1
3	12k ± 1
5	10k ± 1
6	24k ± 1,5

Finding the CONTINUED FRACTION of a SQUARE ROOT $\sqrt{D}$ and using the relationship

$$Q_n = \frac{D - P_n^2}{Q_{n-1}} \qquad (13)$$

for the nth CONVERGENT P_n/Q_n gives

$$P_n^2 \equiv -Q_n Q_{n-1} \pmod{D}. \qquad (14)$$

Therefore, $-Q_n Q_{n-1}$ is a quadratic residue of D. But since $Q_1 = 1$, $-Q_2$ is a quadratic residue, as must be $-Q_2 Q_3$. But since $-Q_2$ is a quadratic residue, so is Q_3, and we see that $(-1)^{n-1} Q_n$ are all quadratic residues of D. This method is not guaranteed to produce all quadratic residues, but can often produce several small ones in the case of large D, enabling D to be factored.

The number of SQUARES $s(n)$ in $\mathbb{Z}_n$ is related to the number $q(n)$ of quadratic residues in $\mathbb{Z}_n$ by

$$q(p^n) = s(p^n) - s\left(p^{n-2}\right) \qquad (15)$$

for $n \geq 3$ (Stangl 1996). Both q and s are MULTIPLICATIVE FUNCTIONS.

Quadratic Sieve

A procedure used in conjunction with DIXON'S FACTORIZATION METHOD to factor large numbers n. Pick values of r given by

$$\lfloor \sqrt{n} \rfloor + k, \quad (1)$$

where $k = 1, 2, \ldots$ and $\lfloor x \rfloor$ is the FLOOR FUNCTION. We are then looking for factors p such that

$$n \equiv r^2 \pmod{p}, \quad (2)$$

which means that only numbers with LEGENDRE SYMBOL $(n/p) = 1$ (less than $N = \pi(d)$ for TRIAL DIVISOR d, where $\pi(d)$ is the PRIME COUNTING FUNCTION) need be considered. The set of PRIMES for which this is true is known as the FACTOR BASE. Next, the CONGRUENCES

$$x^2 \equiv n \pmod{p} \quad (3)$$

must be solved for each p in the FACTOR BASE. Finally, a sieve is applied to find values of $f(r) = r^2 - n$ which can be factored completely using only the FACTOR BASE. GAUSSIAN ELIMINATION is then used as in DIXON'S FACTORIZATION METHOD in order to find a product of the $f(r)$s, yielding a PERFECT SQUARE.

The method requires about $\exp\left(\sqrt{\ln n \, \ln \ln n}\right)$ steps, improving on the CONTINUED FRACTION FACTORIZATION ALGORITHM by removing the 2 under the SQUARE ROOT (Pomerance 1996). The use of multiple POLYNOMIALS gives a better chance of factorization, requires a shorter sieve interval, and is well suited to parallel processing.

Quadratic Surd

QUADRATIC IRRATIONAL NUMBER

Quadratic Surface

A second-order ALGEBRAIC SURFACE given by the general equation

$$ax^2 + by^2 + cz^2 + 2fyz + 2gzx + 2hxy + 2px + 2py + 2rz + d = 0. \quad (1)$$

Quadratic surfaces are also called quadrics, and there

are 17 standard-form types. A quadratic surface intersects every plane in a (proper or degenerate) CONIC SECTION. In addition, the CONE consisting of all tangents from a fixed point to a quadratic surface cuts every plane in a CONIC SECTION, and the points of contact of this CONE with the surface form a CONIC SECTION (Hilbert and Cohn-Vossen 1999, p. 12).

Define

$$e = \begin{bmatrix} a & h & g \\ h & b & f \\ g & f & c \end{bmatrix} \tag{2}$$

$$E = \begin{bmatrix} a & h & g & p \\ h & b & f & q \\ g & f & c & r \\ p & q & r & d \end{bmatrix} \tag{3}$$

$$\rho_3 = \text{rank } e \tag{4}$$

$$\rho_4 = \text{rank } E \tag{5}$$

$$\Delta = \det E, \tag{6}$$

and k_1, k_2, as k_3 are the roots of

$$\begin{vmatrix} a-x & h & g \\ h & b-x & f \\ g & f & c-x \end{vmatrix} = 0. \tag{7}$$

Also define

$$k \equiv \begin{cases} 1 & \text{if the signs of nonzero } ks \text{ are the same} \\ 0 & \text{otherwise.} \end{cases} \tag{8}$$

Then the following table enumerates the 17 quadrics and their properties (Beyer 1987).

Surface	Equation	ρ_3	ρ_4	sgn(Δ)	k
Coincident PLANES	$x^2 = 0$	1	1		
Ellipsoid (Imaginary)	$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=-1$	3	4	+	1
ELLIPSOID (Real)	$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$	3	4	(−)	1
Elliptic Cone (Imaginary)	$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=0$	3	3		1
ELLIPTIC CONE (Real)	$z^2=\frac{x^2}{a^2}+\frac{y^2}{b^2}$	3	3		0
Elliptic Cylinder (Imaginary)	$\frac{x^2}{a^2}+\frac{y^2}{b^2}=-1$	2	3		1
ELLIPTIC CYLINDER (Real)	$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$	2	3		1
ELLIPTIC PARABOLOID	$z=\frac{x^2}{a^2}+\frac{y^2}{b^2}$	2	4	(−)	1
HYPERBOLIC CYLINDER	$\frac{x^2}{a^2}-\frac{y^2}{b^2}=-1$	2	3		0
HYPERBOLIC PARABOLOID	$z=\frac{y^2}{a^2}-\frac{x^2}{b^2}$	2	4	+	0
HYPERBOLOID of one Sheet	$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=1$	3	4	+	0
HYPERBOLOID of two Sheets	$\frac{x^2}{a^2}+\frac{y^2}{b^2}-\frac{z^2}{c^2}=-1$	3	4	(−)	0
Intersecting Planes (Imaginary)	$\frac{x^2}{a^2}+\frac{y^2}{b^2}=0$	2	2		1
Intersecting PLANES (Real)	$\frac{x^2}{a^2}-\frac{y^2}{b^2}=0$	2	2		0
PARABOLIC CYLINDER	$x^2+2rz=0$	1	3		
Parallel Planes (Imaginary)	$x^2=-a^2$	1	2		
Parallel PLANES (Real)	$x^2=a^2$	1	2		

Of the non-degenerate quadratic surfaces, the ELLIPTIC (and usual) CYLINDER, HYPERBOLIC CYLINDER, ELLIPTIC (and usual) CONE are RULED SURFACES, while the one-sheeted HYPERBOLOID and HYPERBOLIC PARABOLOID are DOUBLY RULED SURFACES.

A curve in which two arbitrary quadratic surfaces in arbitrary positions intersect cannot meet any plane in more than four points (Hilbert and Cohn-Vossen 1999, p. 24).

Quadratrix of Hippias

The quadratrix was discovered by Hippias of Elias in 430 BC, and later studied by Dinostratus in 350 BC (MacTutor Archive). It can be used for ANGLE TRISECTION or, more generally, division of an ANGLE into any integral number of equal parts, and CIRCLE SQUARING. In POLAR COORDINATES,

$$\pi\rho = 2r\theta \csc \theta,$$

so

$$r = \frac{\rho\pi \sin \theta}{\theta},$$

which is proportional to the COCHLEOID.

Quadrature

The word quadrature has (at least) three incompatible meanings. Integration by quadrature either means solving an INTEGRAL analytically (i.e., symbolically in terms of known functions), or solving of an integral numerically (e.g., GAUSSIAN QUADRATURE, QUADRATURE FORMULAS). Ueberhuber (1997, p. 71) uses the word "quadrature" to mean numerical computation of a univariate INTEGRAL, and "CUBATURE" to mean numerical computation of a MULTIPLE INTEGRAL.

The word quadrature is also used to mean SQUARING: the construction of a square using only COMPASS and STRAIGHTEDGE which has the same AREA as a given geometric figure. If quadrature is possible for a PLANE figure, it is said to be QUADRABLE.

For a function tabulated at given values x_i (so the ABSCISSAS cannot be chosen at will), write the function ϕ as a sum of ORTHONORMAL FUNCTIONS p_j satisfying

$$\int_a^b p_i(x)p_j(x)W(x)dx = \delta_{ij} \tag{1}$$

as

$$\phi(x) = \sum_{j=0}^{\infty} a_j p_j(x), \tag{2}$$

and plug into

$$\int_a^b \phi(x)W(x)\,dx = \int_a^b \sum_{j=1}^{m} \frac{\pi(x)W(x)}{(x - xj)\pi'(x_j)} dx\, f(x_j)$$

$$\equiv \sum_{j=1}^{m} w_j f(x_j), \tag{3}$$

giving

$$\int_a^b \sum_{j=0}^{\infty} a_j p_j(x)W(x)dx = \sum_{i=1}^{n} w_i \left[\sum_{j=0}^{\infty} a_j p_j(x_j)\right]. \tag{4}$$

But we wish this to hold for all degrees of approximation, so

$$a_j \int_a^b p_j(x)W(x)dx = a_j \sum_{i=1}^{n} w_i p_j(x_i) \tag{5}$$

$$\int_a^b p_j(x)W(x)dx = \sum_{i=1}^{n} w_i p_j(x_i). \tag{6}$$

Setting $i = 0$ in (1) gives

$$\int_a^b p_0(x)p_j(x)W(x)dx = \delta_{0j}. \tag{7}$$

The zeroth order orthonormal function can always be taken as $p_0(x) = 1$, so (7) becomes

$$\int_a^b p_j(x)W(x)dx = \delta_{0j} \tag{8}$$

$$= \sum_{i=1}^{n} w_i p_j(x_i), \tag{9}$$

where (6) has been used in the last step. We therefore have the MATRIX equation

$$\begin{bmatrix} p_0(x_1) & \cdots & p_0(x_n) \\ p_0(x_1) & \cdots & p_1(x_n) \\ \vdots & \ddots & \vdots \\ p_{n-1}(x_1) & \cdots & p_{n-1}(x_n) \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_n \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \tag{10}$$

which can be inverted to solve for the w_is (Press *et al.* 1992).

NEWTON-COTES FORMULAS

Quadri-Amicable Number

AMICABLE QUADRUPLE

Quadric

A quadric is a QUADRATIC SURFACE. A surface OF THE FORM

$$\frac{x^2}{a^2+\theta}+\frac{y^2}{b^2+\theta}+\frac{z^2}{c^2+\theta}=1$$

is also called a quadric, and θ is said to be the parameter of the quadric.

See also QUADRATIC SURFACE

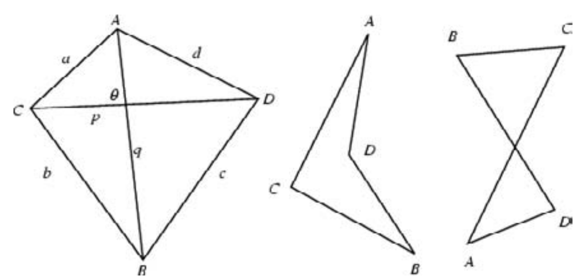
Quadrifolium

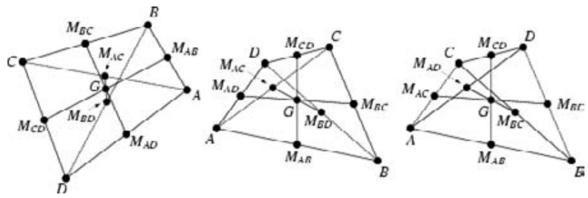
The ROSE with $n=2$. It has polar equation



$$r=a\sin(2\theta),$$

and Cartesian form

$$(x^2+y^2)^3=4a^2x^2y^2.$$



See also BIFOLIUM, FOLIUM, ROSE, TRIFOLIUM

Quadrilateral

A four-sided POLYGON sometimes (but not very often) also known as a tetragon. If not explicitly stated, all four VERTICES are generally taken to lie in a PLANE. If the points do not lie in a PLANE, the quadrilateral is called a SKEW QUADRILATERAL. There are three topological types of quadrilaterals (Wenninger 1983, p. 50): convex quadrilaterals (left figure), concave quadrilaterals (middle figure), and crossed quadrilaterals (or butterflies, or bow-ties; right figure).

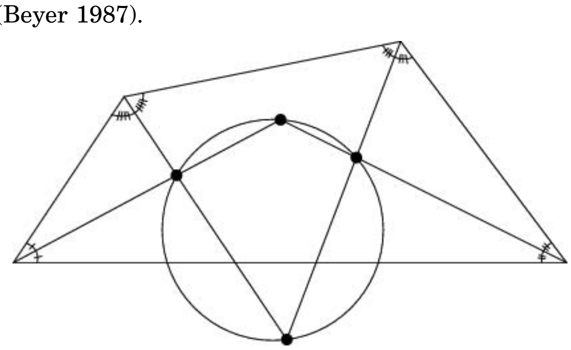
For a planar convex quadrilateral (left figure above), let the lengths of the sides be a, b, c, and d, the SEMIPERIMETER s, and the DIAGONALS p and q. The DIAGONALS are PERPENDICULAR IFF $a^2+c^2=b^2+d^2$.. Given any five points in the plane, four will always form a convex quadrilateral. This result is a special case of the so-called HAPPY END PROBLEM (Hoffman 1998, pp. 74–78).

The centroid of the vertices of a quadrilateral occurs at the point of intersection of the BIMEDIANS (i.e., the lines $M_{AB}M_{CD}$ and $M_{AD}M_{BC}$ joining pairs of opposite MIDPOINTS) (Honsberger 1995, pp. 36–37). In addition, it is the MIDPOINT of the line $M_{AC}M_{BD}$ connecting the midpoints of the diagonals AC and BD (Honsberger 1995, pp. 39–40).

An equation for the sum of the squares of side lengths is

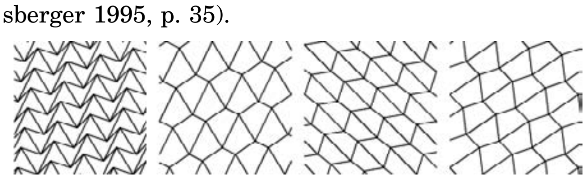
$$a^2+b^2+c^2+d^2=p^2+q^2+4x^2, \tag{1}$$

where x is the length of the line joining the MIDPOINTS of the DIAGONALS (Casey 1888, p. 22). The AREA of a quadrilateral is given by



$$K=\tfrac{1}{2}pq\sin\theta \tag{2}$$

$$=\tfrac{1}{4}(b^2+d^2-a^2-c^2)\tan\theta \tag{3}$$



$$=\tfrac{1}{4}\sqrt{4p^2q^2-(b^2+d^2-a^2-c^2)^2} \tag{4}$$

$$=\sqrt{(s-a)(s-b)(s-c)(s-d)-abcd\cos^2\left[\tfrac{1}{2}(A+B)\right]}, \tag{5}$$

where (4) is known as BRETSCHNEIDER'S FORMULA (Beyer 1987).

The four ANGLE BISECTORS of a quadrilateral intersect adjacent bisectors in four CONCYCLIC points (Honsberger 1995, p. 35).

Any non-self-intersecting quadrilateral tiles the plane.

There is a relationship between the six distances d_{12}, d_{13}, d_{14}, d_{23}, d_{24}, and d_{34} between the four points of a quadrilateral (Weinberg 1972):

$$\begin{aligned}0={}&d_{12}^4d_{34}^2+d_{13}^4d_{24}^2+d_{14}^4d_{23}^2+d_{23}^4d_{14}^2+d_{24}^4d_{13}^2+d_{34}^4d_{12}^2\\&+d_{12}^2d_{23}^2d_{31}^2+d_{12}^2d_{24}^2d_{41}^2+d_{13}^2d_{34}^2d_{41}^2\\&+d_{23}^2d_{34}^2d_{42}^2-d_{12}^2d_{23}^2d_{34}^2-d_{13}^2d_{32}^2d_{24}^2\\&-d_{12}^2d_{24}^2d_{43}^2-d_{14}^2d_{42}^2d_{23}^2-d_{13}^2d_{34}^2d_{42}^2\\&-d_{14}^2d_{43}^2d_{32}^2-d_{23}^2d_{31}^2d_{14}^2+d_{21}^2d_{13}^2d_{34}^2\\&-d_{24}^2d_{41}^2d_{13}^2-d_{21}^2d_{14}^2d_{43}^2-d_{31}^2d_{12}^2d_{24}^2\\&-d_{32}^2d_{21}^2d_{14}^2.\end{aligned} \tag{6}$$

This can be most simply derived by setting the left side of the CAYLEY-MENGER DETERMINANT

$$288V^2=\begin{vmatrix}0 & 1 & 1 & 1 & 1\\ 1 & 0 & d_{12}^2 & d_{13}^2 & d_{14}^2\\ 1 & d_{21}^2 & 0 & d_{23}^2 & d_{24}^2\\ 1 & d_{31}^2 & d_{32}^2 & 0 & d_{34}^2\\ 1 & d_{41}^2 & d_{42}^2 & d_{43}^2 & 0\end{vmatrix} \tag{7}$$

equal to 0 (corresponding to a TETRAHEDRON of volume 0), thus giving a relationship between the DISTANCES between vertices of a planar quadrilateral (Uspensky 1948, p. 256).

A special type of quadrilateral is the CYCLIC QUADRILATERAL, for which a CIRCLE can be circumscribed so that it touches each VERTEX. For BICENTRIC QUADRILATERALS, the CIRCUMCIRCLE and INCIRCLE satisfy

$$2r^2(R^2-s^2)=(R^2-s^2)-4r^2s^2, \tag{8}$$

where R is the CIRCUMRADIUS, r in the INRADIUS, and s is the separation of centers. A quadrilateral with two sides PARALLEL is called a TRAPEZOID.

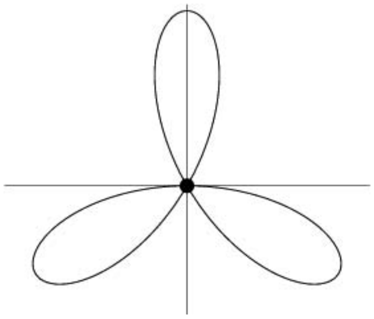
Quadrivium

A word derived from the Latin roots *quad-* (four) and *via* (ways, roads), therefore a crossing of four roads. In medieval universities, the quadrivium consisted of the four subjects in the upper division of the seven liberal arts: ARITHMETIC, astronomy, GEOMETRY, and music.



See also TRIVIUM

Quadruple

A group of four elements, also called a QUADRUPLET or TETRAD.

Quadruplet

QUADRUPLE

Quadtree

A TREE having four branches at each node. Quadtrees are used in the construction of some multidimensional databases (e.g., cartography, computer graphics, and image processing). For a d-D tree, the expected number of comparisons over all pairs of integers for successful and unsuccessful searches are given analytically for $d=2$ and numerically for $d\geq 3$ by Finch.

Quantic

An m-ary n-ic polynomial (i.e., a HOMOGENEOUS POLYNOMIAL with constant COEFFICIENTS of degree n in m independent variables).

See also ALGEBRAIC INVARIANT, FUNDAMENTAL SYSTEM, p-ADIC NUMBER, SYZYGIES PROBLEM

Quantified System

A quantified system of real algebraic equations and inequalities in variables $\{x_1, \ldots, x_n\}$ is an expression

$$QS = Q_1(y_1)(Q_2)(y_2)\cdots Q_m(y_m)S(x_1,\ldots,x_n;y_1,\ldots,y_m),$$

where Q is a QUANTIFIER ($\exists$ or $\forall$) and S is a system of real algebraic equations and inequalities in $\{x_1\ldots,x_n;\ y_1,\ldots y_m\}$. By TARSKI'S THEOREM, the solution set of a quantified system of real algebraic equations and inequalities is a SEMIALGEBRAIC SET.

Quantifier

One of the operations EXISTS $\exists$ or FOR ALL $\forall$. However, there also exist more exotic branches of logic which use quantifiers other than these two.

References

Hall, C. and O'Donnell, J. "Computing with Quantifiers." §3.2 in *Discrete Mathematics Using a Computer.* London: Springer-Verlag, pp. 98–100, 2000.

Quantifier Elimination

Quantifier elimination is the removal of all QUANTIFIERS ($\forall$ and $\exists$) from a quantified system. A first-order theory allows quantifier elimination if, for each quantified formula, there exists an equivalent quantifier-free formula. Examples of such theories include the real numbers with +, *, =, and >, and the theory of complex numbers with +, *, and =. Quantifier elimination is implemented in *Mathematica* as `Resolve[`*expr*`]`.

Unfortunately, it has been proven that the worst-case time complexity for real quantifier elimination is doubly exponential in the number of QUANTIFIER blocks (Weispfenning 1985, Davenport and Heintz 1988, Heintz *et al.* 1989, Caviness and Johnson 1998).

Quantile

The kth n-tile P_k is that value of x, say x_k, which corresponds to a CUMULATIVE FREQUENCY of Nk/n. If

$n = 4$, the quantity is called a QUARTILE, and if $n = 100$, it is called a PERCENTILE.

See also PERCENTILE, QUARTILE

Quantity

See also EXPRESSION

Quantization Efficiency

Quantization is a nonlinear process which generates additional frequency components (Thompson *et al.* 1986). This means that the signal is no longer band-limited, so the SAMPLING THEOREM no longer holds. If a signal is sampled at the NYQUIST FREQUENCY, information will be lost. Therefore, sampling faster than the NYQUIST FREQUENCY results in detection of more of the signal and a lower signal-to-noise ratio [SNR]. Let β be the OVERSAMPLING ratio and define

$$\eta_Q \equiv \frac{\mathrm{SNR}_{\mathrm{quant}}}{\mathrm{SNR}_{\mathrm{unquant}}}.$$

Then the following table gives values of η_Q for a number of parameters.

Quantization Levels	$\eta_Q(\beta = 1)$	$\eta_Q(\beta = 2)$
2	0.64	0.74
3	0.81	0.89
4	0.88	0.94

The Very Large Array of 27 radio telescopes in Socorro, New Mexico uses three-level quantization at $\beta = 1$, so $\eta_Q = 0.81$.

Quartic Curve

A general plane quartic curve is a curve OF THE FORM

$$Ax^4 + By^4 + Cx^3y + Dx^2y^2 + Exy^3 + Fx^3 + Gy^3$$
$$+Hx^2y + Ixy^2 + Jx^2 + Ky^2 + Lxy + Mx + Ny + O = 0. \tag{1}$$

The incidence relations of the 28 bitangents of the general quartic curve can be put into a ONE-TO-ONE correspondence with the vertices of a particular POLYTOPE in 7-D space (Coxeter 1928, Du Val 1931). This fact is essentially similar to the discovery by Schoutte (1910) that the 27 SOLOMON'S SEAL LINES on a CUBIC SURFACE can be connected with a POLYTOPE in 6-D space (Du Val 1931). A similar but less complete relation exists between the tritangent planes of the canonical curve of genus 4 and an 8-D POLYTOPE (Du Val 1931).

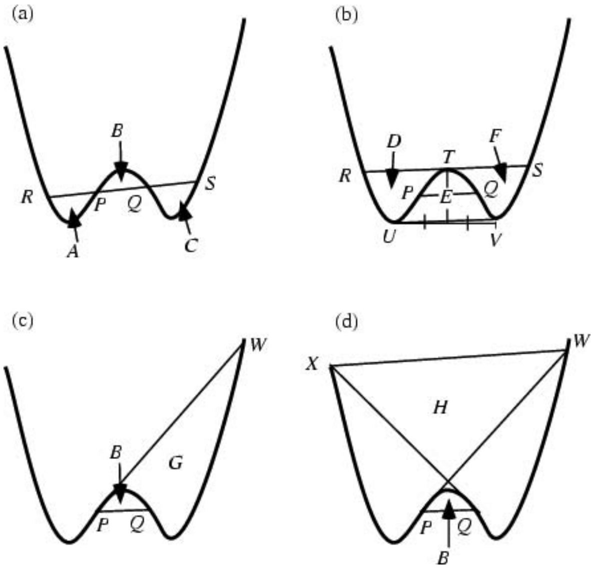
The maximum number of DOUBLE POINTS for a nondegenerate quartic curve is three.

A quartic curve OF THE FORM

$$y^2 = (x-a)(x-\xi)(x-\gamma)(x-\delta) \tag{2}$$

can be written

$$\left(\frac{y}{x-\alpha}\right)^2 = \left(1 - \frac{\beta-\alpha}{x-\alpha}\right)\left(1 - \frac{\gamma-\alpha}{x-\alpha}\right)\left(1 - \frac{\delta-\alpha}{x-\alpha}\right), \tag{3}$$



and so is CUBIC in the coordinates

$$X = \frac{1}{x-\alpha} \tag{4}$$

$$Y = \frac{y}{x-\alpha^2}. \tag{5}$$

This transformation is a BIRATIONAL TRANSFORMA-

TION.

Let P and Q be the INFLECTION POINTS and R and S the intersections of the line PQ with the curve in Figure (a) above. Then

$$A = C \tag{6}$$

$$B = 2A. \tag{7}$$

In Figure (b), let UV be the double tangent, and T the point on the curve whose x coordinate is the average of the x coordinates of U and V. Then $UV \| PQ \| RS$ and

$$D = F \tag{8}$$

$$E = \sqrt{2}D. \tag{9}$$

In Figure (c), the tangent at P intersects the curve at W. Then

$$G = 8B. \tag{10}$$

Finally, in Figure (d), the intersections of the tangents at P and Q are W and X. Then

$$H = 27B \tag{11}$$

(Honsberger 1991).

Quartic Equation

A general quartic equation (also called a BIQUADRATIC EQUATION) is a fourth-order POLYNOMIAL OF THE FORM

$$z^4 + a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0. \tag{1}$$

The ROOTS of this equation satisfy NEWTON'S RELATIONS:

$$x_1 + x_2 + x_3 + x_4 = -a_3 \tag{2}$$

$$x_1x_2 + x_1x_3 + x_1x_4 + x_2x_3 + x_2x_4 + x_3x_4 = a_2 \tag{3}$$

$$x_1x_2x_3 + x_2x_3x_4 + x_1x_2x_4 + x_1x_3x_4 = -a_1 \tag{4}$$

$$x_1x_2x_3x_4 = a_{0,} \tag{5}$$

where the denominators on the right side are all $a_4 \equiv 1$. Writing the quartic in the standard form

$$x^4 + px^2 + qx + r = 0, \tag{6}$$

the properties of the SYMMETRIC POLYNOMIALS appearing in NEWTON'S RELATIONS then give

$$z_1^2 + z_2^2 + z_3^2 + z_4^2 = -2p \tag{7}$$

$$z_1^3 + z_2^3 + z_3^3 + z_4^3 = -3p \tag{8}$$

$$z_1^4 + z_2^4 + z_3^4 + z_4^4 = 2p^2 - 4r \tag{9}$$

$$z_1^5 + z_2^5 + z_3^5 + z_4^5 = 5pq. \tag{10}$$

Eliminating p, q, and r, respectively, gives the relations

$$z_1z_2\left(p + z_1^2 + z_1z_2 + z_2^2\right) - r = 0 \tag{11}$$

$$z_1^2 z_2 (z_1 + z_2) - qz_1 - r = 0 \tag{12}$$

$$q + pz_2 + z_2^3 = 0, \tag{13}$$

as well as their cyclic permutations.

Ferrari was the first to develop an algebraic technique for solving the general quartic. He applied his technique (which was stolen and published by Cardano) to the equation

$$x^4 + 6x^2 - 60x + 36 = 0 \tag{14}$$

(Smith 1994, p. 207).

The x^3 term can be eliminated from the general quartic (1) by making a substitution OF THE FORM

$$z \equiv x - \lambda, \tag{15}$$

so

$$x^4 + (a_3 - 4\lambda)x^3 + \left(a_2 - 3a_3\lambda + 6\lambda^2\right)x^2$$

$$+(a_1 - 2a_2\lambda + 3a_3\lambda^2 - 4\lambda^3)x$$

$$+(a_0 - a_1\lambda + a_2\lambda^2 - a_3\lambda^3 + \lambda^4). \quad (16)$$

Letting $\lambda = a_3/4$ so

$$z \equiv x - \tfrac{1}{4}a_3 \quad (17)$$

then gives the standard form

$$x^4 + px^2 + qx + r = 0, \quad (18)$$

where

$$p \equiv a_2 - \tfrac{3}{8}a_3^2 \quad (19)$$

$$q \equiv a_1 - \tfrac{1}{2}a_2a_3 + \tfrac{1}{8}a_3^3 \quad (20)$$

$$r \equiv a_0 - \tfrac{1}{4}a_1a_3 + \tfrac{1}{16}a_2a_3^2 - \tfrac{3}{256}a_3^4. \quad (21)$$

Adding and subtracting $x^2u + u^2/4$ to (6) gives

$$\left(x^4 + x^2u + \tfrac{1}{4}u^2\right) - x^2u - \tfrac{1}{4}u^2 + px^2 + qx + r = 0, \quad (22)$$

which can be rewritten

$$\left(x^2 + \tfrac{1}{2}u\right)^2 - \left[(u-p)x^2 - qx + \left(\tfrac{1}{4}u^2 - r\right)\right] = 0 \quad (23)$$

(Birkhoff and Mac Lane 1965). The first term is a perfect square P^2, and the second term is a perfect square Q^2 for those u such that

$$q^2 = 4(u-p)\left(\tfrac{1}{4}u^2 - r\right). \quad (24)$$

This is the resolvent CUBIC, and plugging a solution u_1 back in gives

$$P^2 - Q^2 = (P+Q)(P-Q), \quad (25)$$

so (23) becomes

$$\left(x^2 + \tfrac{1}{2}u_1 + Q\right)\left(x^2 + \tfrac{1}{2}u_1 - Q\right), \quad (26)$$

where

$$Q \equiv Ax - B \quad (27)$$

$$A \equiv \sqrt{u_1 - p} \quad (28)$$

$$B \equiv -\frac{q}{2A}. \quad (29)$$

Let y_1 be a REAL ROOT of the resolvent CUBIC EQUATION

$$y^3 - a_2y^2 + (a_1a_3 - 4a_0)y + \left(4a_2a_0 - a_1^2 - a_3^2a_0\right) = 0. \quad (30)$$

The four ROOTS are then given by the ROOTS of the equation

$$x^2 + \tfrac{1}{2}\left(a_3 \pm \sqrt{a_3^2 - 4a_2 + 4y_1}\right) + \tfrac{1}{2}\left(y_1 \mp \sqrt{y_1^2 - 4a_0}\right) = 0, \quad (31)$$

which are

$$z_1 = -\tfrac{1}{4}a_3 + \tfrac{1}{2}R + \tfrac{1}{2}D \quad (32)$$

$$z_2 = -\tfrac{1}{4}a_3 + \tfrac{1}{2}R - \tfrac{1}{2}D \quad (33)$$

$$z_3 = -\tfrac{1}{4}a_3 - \tfrac{1}{2}R + \tfrac{1}{2}E \quad (34)$$

$$z_4 = -\tfrac{1}{4}a_3 - \tfrac{1}{2}R - \tfrac{1}{2}E, \quad (35)$$

where

$$R \equiv \sqrt{\tfrac{1}{4}a_3^2 - a_2 + y_1} \quad (36)$$

$$D \equiv \begin{cases} \sqrt{\tfrac{3}{4}a_3^2 - R^2 - 2a_2 - \tfrac{1}{4}(4a_3a_2 - 8a_1 - a_3^3)R^{-1}} & R \neq 0 \\ \sqrt{\tfrac{3}{4}a_3^2 - 2a_2 + 2\sqrt{y_1^2 - 4a_0}} & R = 0 \end{cases} \quad (37)$$

$$E \equiv \begin{cases} \sqrt{\tfrac{3}{4}a_3^2 - R^2 - 2a_2 - \tfrac{1}{4}(4a_3a_2 - 8a_1 - a_3^3)R^{-1}} & R \neq 0 \\ \sqrt{\tfrac{3}{4}a_3^2 - 2a_2 - 2\sqrt{y_1^2 - 4a_0}} & R = 0 \end{cases} \quad (38)$$

Another approach to solving the quartic (6) defines

$$\alpha \equiv (x_1 + x_2)(x_3 + x_4) = -(x_1 + x_2)^2 \quad (39)$$

$$\beta \equiv (x_1 + x_3)(x_2 + x_4) = -(x_1 + x_3)^2 \quad (40)$$

$$\gamma \equiv (x_1 + x_4)(x_2 + x_3) = -(x_2 + x_3)^2, \quad (41)$$

where the second forms follow from

$$x_1 + x_2 + x_3 + x_4 = -a_3 = 0, \quad (42)$$

and defining

$$h(x) \equiv (x-\alpha)(x-\beta)(x-\gamma) \quad (43)$$

$$= x^3 - (\alpha+\beta+\gamma)x^2 + (\alpha\beta + \alpha\gamma + \beta\gamma)x - \alpha\beta\gamma. \quad (44)$$

This equation can be written in terms of the original coefficients p, q, and r as

$$h(x) = x^3 - 2px^2 + (p^2 - 4r)x + q^2. \quad (45)$$

The roots of this CUBIC EQUATION then give α, β, and γ, and the equations (39) to (41) can be solved for the four roots x_i of the original quartic (Faucette 1996).

Quartic Graph

K_5 $Ci_{1,2}(6)$ $Ci_{1,3}(7)$

A quartic graph is a GRAPH which is 4-REGULAR. The unique quartic graph on five nodes is the COMPLETE GRAPH K_5, and the unique quartic graph on six nodes is the CIRCULANT GRAPH $Ci_{1,2}(6)$. There are two quartic graphs on seven nodes, one of which is the CIRCULANT GRAPH $Ci_{1,3}(7)$. The numbers of connected quartic graphs on $n = 1, 2, \ldots$ nodes are 0, 0, 0, 0, 1, 1, 2, 6, 16, 59, ... (Sloane's A006820), the numbers of not necessarily connected quartic graphs are 0, 0, 0, 0, 1, 1, 2, 6, 16, 60, ... (Sloane's A033301), and the numbers of disconnected quartic graphs for $n = 10, 11, \ldots$ are 1, 1, 3, 8, 25, 88, ... (Sloane's A033483; Read and Wilson 1998).
The following tables gives polyhedra whose SKELETONS are quartic.

POLYHEDRON	nodes
OCTAHEDRON	6
CUBOCTAHEDRON	12
SMALL RHOMBICUBOCTAHEDRON	24
ICOSIDODECAHEDRON	30
SMALL RHOMBICOSIDODECAHEDRON	60

Quartile

One of the four divisions of observations which have been grouped into four equal-sized sets based on their RANK. The quartile including the top RANKED members is called the first quartile and denoted Q_1. The other quartiles are similarly denoted Q_2, Q_3, and Q_4. For N data points with N OF THE FORM $4n+5$ (for $n = 0, 1, \ldots$), the HINGES are identical to the first and third quartiles.

Quasiamicable Pair

Let $\sigma(m)$ be the DIVISOR FUNCTION of m. Then two numbers m and n are a quasiamicable pair if

$$\sigma(m) = \sigma(n) = m + n + 1.$$

The first few are (48, 75), (140, 195), (1050, 1575), (1648, 1925), ... (Sloane's A005276). Quasiamicable numbers are sometimes called BETROTHED NUMBERS or REDUCED AMICABLE PAIRS.

Quasigroup

A GROUPOID S such that for all $a, b \in S$, there exist unique $x, y \in S$ such that

$$ax = b$$

$$ya = b.$$

No other restrictions are applied; thus a quasigroup need not have an IDENTITY ELEMENT, not be associative, etc. Quasigroups are precisely GROUPOIDS whose multiplication tables are LATIN SQUARES. A quasigroup can be empty.

Quasiperfect Number

A least ABUNDANT NUMBER, i.e., one such that

$$\sigma(n) = 2n + 1.$$

Quasiperfect numbers are therefore the sum of their nontrivial DIVISORS. No quasiperfect numbers are known, although if any exist, they must be greater than 10^{35} and have seven or more DIVISORS. Singh (1997) called quasiperfect numbers SLIGHTLY EXCESSIVE NUMBERS.

Quasiperiodic Function

WEIERSTRASS SIGMA FUNCTION, WEIERSTRASS ZETA FUNCTION

Quasiperiodic Motion

The type of motion executed by a DYNAMICAL SYSTEM containing two incommensurate frequencies.

Quasirandom Sequence

A sequence of n-tuples that fills n-space more uniformly than uncorrelated random points. Such a sequence is extremely useful in computational problems where numbers are computed on a grid, but it is not known in advance how fine the grid must be to obtain accurate results. Using a quasirandom sequence allows stopping at any point where convergence is observed, whereas the usual approach of halving the interval between subsequent computations requires a huge number of computations between stopping points.

Quasiregular Polyhedron

A quasiregular polyhedron is the solid region interior to two DUAL REGULAR POLYHEDRA with SCHLÄFLI SYMBOLS $\{p,q\}$. and $\{q,p\}$. Quasiregular polyhedra are denoted using a SCHLÄFLI SYMBOL OF THE FORM $\begin{Bmatrix}p\\q\end{Bmatrix}$, with

$$\begin{Bmatrix}p\\q\end{Bmatrix}=\begin{Bmatrix}q\\p\end{Bmatrix}. \tag{1}$$

Quasiregular polyhedra have two kinds of regular faces with each entirely surrounded by faces of the other kind, equal sides, and equal dihedral angles. They must satisfy the Diophantine inequality

$$\frac{1}{p}+\frac{1}{q}+\frac{1}{r}>1. \tag{2}$$

But $p,q \geq 3$, so r must be 2. This means that the possible quasiregular polyhedra have symbols $\begin{Bmatrix}3\\3\end{Bmatrix}$, $\begin{Bmatrix}3\\4\end{Bmatrix}$, and $\begin{Bmatrix}3\\5\end{Bmatrix}$. Now

$$\begin{Bmatrix}3\\3\end{Bmatrix}=\{3,4\} \tag{3}$$

is the OCTAHEDRON, which is a regular PLATONIC SOLID and not considered quasiregular. This leaves only two convex quasiregular polyhedra: the CUBOCTAHEDRON $\begin{Bmatrix}3\\4\end{Bmatrix}$ and the ICOSIDODECAHEDRON $\begin{Bmatrix}3\\5\end{Bmatrix}$.

If nonconvex polyhedra are allowed, then additional quasiregular polyhedra the DODECADODECAHEDRON $\{5,\frac{5}{2}\}$ GREAT ICOSIDODECAHEDRON $\{3,\frac{5}{2}\}$, as well as 12 others (Hart).

For faces to be equatorial $\{h\}$,

$$h=\sqrt{4N_1+1}-1. \tag{4}$$

The EDGES of quasiregular polyhedra form a system of GREAT CIRCLES: the OCTAHEDRON forms three SQUARES, the CUBOCTAHEDRON four HEXAGONS, and the ICOSIDODECAHEDRON six DECAGONS. The VERTEX FIGURES of quasiregular polyhedra are RECTANGLES (Hart). The EDGES are also all equivalent, a property shared only with the completely regular PLATONIC SOLIDS.

Quasi-Unipotent Group

A group G is quasi-unipotent if every element of G of order p is unipotent for all primes p such that G has p-rank ≥ 3.

Quasi-Unipotent Problem

Quasithin Theorem

Quaternary

The base 4 method of counting in which only the digits 0, 1, 2, and 3 are used. The following table gives the quaternary equivalents of the first few decimal numbers.

1	1	11	23	21	111
2	2	12	30	22	112
3	3	13	31	23	113
4	10	14	32	24	120
5	11	15	33	25	121
6	12	16	100	26	122
7	13	17	101	27	123
8	20	18	102	28	130
9	21	19	103	29	131
10	22	20	110	30	132

These digits have the following multiplication table.

$\times$	0	1	2	3
0	0	0	0	0
1	0	1	2	3
2	0	2	10	12
3	0	3	12	21

Quaternary Tree

Quadtree

Quaternion

A member of a *noncommutative* division algebra first invented by William Rowan Hamilton. The idea for quaternions occurred to him while be was walking along the Royal Canal on his way to a meeting of the Irish Academy, and Hamilton was so pleased with his discovery that he scratched the fundamental formula of quaternion algebra,

$$i^2 = j^2 = k^2 = ijk = -1, \qquad (1)$$

into the stone of the Brougham bridge (Mishchenko and Solovyov 2000). The set of quaternions is denoted $\mathbb{H}$, and the quaternions are a single example of a more general class of hypercomplex numbers discovered by Hamilton. While the quaternions are not commutative, they are associative, and they form a group known as the quaternion group.

The quaternions can be represented using complex 2×2 matrices

$$H = \begin{bmatrix} z & w \\ -\bar{w} & \bar{z} \end{bmatrix} = \begin{bmatrix} a+ib & c+id \\ -c+id & a-ib \end{bmatrix}, \tag{2}$$

where z and w are COMPLEX NUMBERS, a, b, c, and d are REAL, and $\bar{z}$ is the COMPLEX CONJUGATE of z. A quaternion can be represented using Quaternion[a, b, c, d] in the *Mathematica* add-on package Algebra`Quaternions` (which can be loaded with the command << Algebra`), where a, b, c, and d are *explicit real numbers.*

By analogy with the COMPLEX NUMBERS being representable as a sum of REAL and IMAGINARY PARTS, $a \cdot 1 + bi$, a quaternion can also be written as a linear combination

$$H = a\mathsf{U} + b\mathsf{I} + c\mathsf{J} + d\mathsf{K} \tag{3}$$

of the four matrices

$$\mathsf{U} \equiv \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{4}$$

$$\mathsf{I} \equiv \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix} \tag{5}$$

$$\mathsf{J} \equiv \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \tag{6}$$

$$\mathsf{K} \equiv \begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix}. \tag{7}$$

(Note that here, U is used to denote the IDENTITY MATRIX, not I.) The matrices are closely related to the PAULI SPIN MATRICES σ_x, σ_y, σ_z, combined with the IDENTITY MATRIX. From the above definitions, it follows that

$$\mathsf{I}^2 = -\boldsymbol{U} \tag{8}$$

$$\mathsf{J}^2 = -\boldsymbol{U} \tag{9}$$

$$\mathsf{K}^2 = -\boldsymbol{U} \tag{10}$$

Therefore I, J, and K are three essentially different solutions of the matrix equation

$$\mathsf{X}^2 = -\mathsf{U}, \tag{11}$$

which could be considered the square roots of the negative identity matrix. A LINEAR COMBINATION of basis quaternions with integer coefficients is sometimes called a HAMILTONIAN INTEGER.

In $\mathbb{R}^4$, the basis of the quaternions can be given by

$$i \equiv \begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{bmatrix} \tag{12}$$

$$j \equiv \begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix} \tag{13}$$

$$k \equiv \begin{bmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix} \tag{14}$$

$$1 \equiv \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \tag{15}$$

The quaternions satisfy the following identities, sometimes known as HAMILTON'S RULES,

$$i^2 = j^2 = k^2 = -1 \tag{16}$$

$$ij = -ji = k \tag{17}$$

$$jk = -kj = i \tag{18}$$

$$ki = -ik = j. \tag{19}$$

They have the following multiplication table.

	1	i	j	k
1	1	i	j	k
i	i	-1	k	$-j$
j	j	$-k$	-1	i
k	k	j	$-i$	-1

The quaternions ± 1, $\pm i$, $\pm j$, and $\pm k$ form a NON-ABELIAN GROUP of order eight (with multiplication as the group operation) known as Q_8 of $\mathbb{H}$.

The quaternions can be written in the form

$$a = a_1 + a_2 i + a_3 j + a_4 k. \tag{20}$$

The conjugate quaternion is given by

$$\bar{a} = a_1 - a_2 i - a_3 j - a_4 k. \tag{21}$$

The sum of two quaternions is then

$$a + b = (a_1 + b_1) + (a_2 + b_2)i + (a_3 + b_3)j + (a_4 + b_4)k, \tag{22}$$

and the product of two quaternions is

$$\begin{aligned} ab = {} & (a_1b_1 - a_2b_2 - a_3b_3 - a_4b_4) \\ & + (a_1b_2 + a_2b_1 + a_3b_4 - a_4b_3)i \\ & + (a_1b_3 - a_2b_4 + a_3b_1 + a_4b_2)j \\ & + (a_1b_4 + a_2b_3 - a_3b_2 + a_4b_1)k, \end{aligned} \tag{23}$$

so the norm is

$$n(a) = \sqrt{a\bar{a}} = \sqrt{\bar{a}a} = \sqrt{a_1^2 + a_2^2 + a_3^2 + a_4^2}. \tag{24}$$

In this notation, the quaternions are closely related to FOUR-VECTORS.

Quaternions can be interpreted as a SCALAR plus a VECTOR by writing

$$a = a_1 + a_2 i + a_3 j + a_4 k = (a_1, \mathbf{a}), \tag{25}$$

where $\mathbf{a} \equiv [a_2 a_3 a_4]$.. In this notation, quaternion multiplication has the particularly simple form

$$\begin{aligned} q_1 q_2 &= (s_1, \mathbf{v}_1) \cdot (s_2, \mathbf{v}_2) \\ &= (s_1 s_2 - \mathbf{v}_1 \cdot \mathbf{v}_2,\ s_1 \mathbf{v}_2 + s_2 \mathbf{v}_1 + \mathbf{v}_1 \times \mathbf{v}_2). \end{aligned} \tag{26}$$

Division is uniquely defined (except by zero), so quaternions form a DIVISION ALGEBRA. The inverse of a quaternion is given by

$$a^{-1} = \frac{\bar{a}}{a\bar{a}}, \tag{27}$$

and the norm is multiplicative

$$n(ab) = n(a)n(b). \tag{28}$$

In fact, the product of two quaternion norms immediately gives the EULER FOUR-SQUARE IDENTITY.

A rotation about the UNIT VECTOR $\hat{\mathbf{n}}$ by an angle θ can be computed using the quaternion

$$q = (s, \mathbf{v}) = \left(\cos\left(\tfrac{1}{2}\theta\right),\ \hat{\mathbf{n}} \sin\left(\tfrac{1}{2}\theta\right)\right) \tag{29}$$

(Arvo 1994, Hearn and Baker 1996). The components of this quaternion are called EULER PARAMETERS. After rotation, a point $p = (0, \mathbf{p})$ is then given by

$$p' = qpq^{-1} = qp\bar{q}, \tag{30}$$

since $n(q) = 1$. A concatenation of two rotations, first q_1 and then q_2, can be computed using the identity

$$q_2(q_1 p \bar{q}_1)\bar{q}_2 = (q_2 q_1)p(\bar{q}_1 \bar{q}_2) = (q_2 q_1)p\overline{q_2 q_1} \tag{31}$$

(Goldstein 1980).

Queens Problem

What is the maximum number of queens which can be placed on an $n \times n$ CHESSBOARD such that no two attack one another? The answer is n queens, which gives eight queens for the usual 8×8 board (Madachy 1979; Steinhaus 1983, p. 29). The *number* of different ways the n queens can be placed on an $n \times n$ chessboard so that no two queens may attack each other for the first few n are 1, 0, 0, 2, 10, 4, 40, 92, ... (Sloane's A000170; Madachy 1979; Steinhaus 1983, p. 29). The number of rotationally and reflectively distinct solutions are 1, 0, 0, 1, 2, 1, 6, 12, 46, 92, ... (Sloane's A002562; Dudeney 1970; p. 96). The 12 distinct solutions for $n = 8$ are illustrated above, and the remaining 80 are generated by ROTATION and REFLECTION (Madachy 1979, Steinhaus 1983).

The minimum number of queens needed to occupy or attack all squares of an 8×8 board is 5 (Steinhaus 1983, p. 29). Dudeney (1970, pp. 95–96) gave the following results for the number of distinct arrangements $N_p(k, n)$ of k queens attacking or occupying every square of an $n \times n$ board for which every queen is attacked ("protected") by at least one other, with the $n = 8$ value given by Steinhaus (1983, p. 29). The 4860 solutions in the $n = 5$ case may be obtained from 638 fundamental arrangements by ROTATION and REFLECTION.

k Queens	$n \times n$	$N_p(k,n)$
2	4	3
3	5	37
3	6	1
4	7	5
5	8	4860

Dudeney (1970, pp. 95–96) also gave the following results for the number of distinct arrangements $N_u(k, n)$ of k queens attacking or occupying every square of an $n \times n$ board for which no two queens attack one another (they are "not protected").

k Queens	$n \times n$	$N_u(k,n)$
1	2	1
1	3	1
3	4	2
3	5	2
4	6	17
4	7	1
5	8	91

Vardi (1991) generalizes the problem from a square chessboard to one with the topology of the TORUS. The number of solutions for n queens with n ODD are 1, 0, 10, 28, 0, 88, ... (Sloane's A007705). Vardi (1991) also considers the toroidal "semiqueens" problem, in which a semiqueen can move like a rook or bishop, but only on POSITIVE broken diagonals. The number of solutions to this problem for n queens with n ODD are 1, 3, 15, 133, 2025, 37851, ... (Sloane's A006717), and 0 for EVEN n.

Velucchi gives the solution to the question, "How many different arrangements of k queens are possible on an order n chessboard?" as 1/8th of the COEFFICIENT of $a^k b^{n^2-k}$ in the POLYNOMIAL

$$p(a,b,n) = \begin{cases} (a+b)^{n2} + 2(a+b)^n (a^2+b^2)^{(n^2-n)/2} \\ \quad +3(a^2+b^2)^{n^2/2} + 2(a^4+b^4)^{n^2/4} & n \text{ even} \\ (a+b)^{n2} + 2(a+b)(a^4+b^4)^{(n^2-1)/4} \\ \quad +(a+b)(a^2+b^2)^{(n^2-1)/2} \\ \quad +4(a+b)^n (a^2+b^2)^{(n^2-n)/2} & n \text{ odd.} \end{cases}$$

Velucchi also considers the nondominating queens problem, which consists of placing n queens on an order n chessboard to leave a maximum number $U(n)$ of unattacked vacant cells. The first few values are 0, 0, 0, 1, 3, 5, 7, 11, 18, 22, 30, 36, 47, 56, 72, 82, ... (Sloane's A001366). The results can be generalized to k queens on an $n \times n$ board.

MINKOWSKI'S QUESTION MARK FUNCTION

Queue

A queue is a special kind of LIST in which elements may only be removed from the bottom by a POP action or added to the top using a PUSH action. Examples of queues include people waiting in line, and submitted jobs waiting to be printed on a printer. The study of queues is called QUEUING THEORY.

See also LIST, PRIORITY QUEUE, QUEUING THEORY, STACK

Queuing Theory

The study of the waiting times, lengths, and other properties of QUEUES.

Quicksort

The fastest known SORTING ALGORITHM (on average, and for a large number of elements), requiring $\mathcal{O}(n \lg n)$ steps. Quicksort is a recursive algorithm which first partitions an array $\{a_i\}_{i=1}^n$ according to several rules (Sedgewick 1978):

1. Some key v is in its final position in the array (i.e., if it is the jth smallest, it is in position a_j).
2. All the elements to the left of a_j are less than or equal to a_j. The elements a_1, a_2, ..., a_{j-1} are called the "left subfile."
3. All the elements to the right of a_j are greater than or equal to a_j. The elements a_{j+1}, ..., a_n are called the "right subfile."

Quicksort was invented by Hoare (1961, 1962), has undergone extensive analysis and scrutiny (Sedgewick 1975, 1977, 1978), and is known to be about twice as fast as the next fastest SORTING algorithm. In the worst case, however, quicksort is a slow n^2 algorithm (and for quicksort, "worst case" corresponds to already sorted).

Quillen-Lichtenbaum Conjecture

A technical CONJECTURE which connects algebraic K-THEORY to Étale cohomology. The conjecture was made more precise by Dwyer and Friedlander (1982). Thomason (1985) established the first half of this conjecture, but the entire conjecture has not yet been established.

Quintic Equation

Unlike quadratic, cubic, and quartic polynomials, the *general* quintic cannot be solved algebraically in terms of a finite number of ADDITIONS, SUBTRACTIONS, MULTIPLICATIONS, DIVISIONS, and ROOT EXTRACTIONS, as rigorously demonstrated by Abel (ABEL'S IMPOSSIBILITY THEOREM) and Galois. However, certain classes of quintic equations can be solved in this manner.

Irreducible quintic equations can be associated with a GALOIS GROUP, which may be a SYMMETRIC GROUP S_n, METACYCLIC GROUP M_n, DIHEDRAL GROUP D_n, ALTERNATING GROUP A_n, or CYCLIC GROUP C_n, as illustrated above.

Euler reduced the general quintic to

$$x^5 - 10qx^2 - p = 0. \tag{1}$$

A quintic also can be algebraically reduced to PRINCIPAL QUINTIC FORM

$$x^5 + a_2x^2 + a_1x + a_0 = 0. \tag{2}$$

By solving a quartic, a quintic can be algebraically reduced to the BRING QUINTIC FORM

$$x^5 - x - a = 0, \tag{3}$$

as was first done by Jerrard. Runge (1885) and Cadenhad and Young found a parameterization of solvable quintics in the form

$$x^5 - ax + b = 0, \tag{4}$$

by showing that all irreducible solvable quintics with COEFFICIENTS of x^4, x^3, and x^2 missing have the following form

$$x^5 + \frac{5\mu^4(4\nu+3)}{\nu^2+1}x + \frac{5\mu^5(2\nu+1)(4\nu+3)}{\nu^2+1} = 0, \tag{5}$$

where μ and ν are RATIONAL. Spearman and Williams (1994) showed that an irreducible quintic OF THE FORM (4) having RATIONAL COEFFICIENTS is solvable by radicals IFF there exist rational numbers $\varepsilon = \pm 1$, $c \geq 0$, and $e \neq 0$ such that

$$a = \frac{5e^4(3 - 4\varepsilon c)}{c^2+1} \tag{6}$$

$$b = \frac{-4e^5(11\varepsilon + 2c)}{c^2+1} \tag{7}$$

The ROOTS are then

$$x_j = e\left(\omega^j u_1 + \omega^{2j} u_2 + \omega^{3j} u_3 + \omega^{4j} u_4\right), \tag{8}$$

where

$$u_1 = \left(\frac{v_1^2 v_3}{D^2}\right)^{1/5} \tag{9}$$

$$u_2 = \left(\frac{v_3^2 v_4}{D^2}\right)^{1/5} \tag{10}$$

$$u_3 = \left(\frac{v_2^2 v_1}{D^2}\right)^{1/5} \tag{11}$$

$$u_4 = \left(\frac{v_4^2 v_2}{D^2}\right)^{1/5} \tag{12}$$

$$v_1 = \sqrt{D} + \sqrt{D - \varepsilon\sqrt{D}} \tag{13}$$

$$v_2 = -\sqrt{D} - \sqrt{D + \varepsilon\sqrt{D}} \tag{14}$$

$$v_3 = -\sqrt{D} + \sqrt{D + \varepsilon\sqrt{D}} \tag{15}$$

$$v_4 = \sqrt{D} - \sqrt{D - \varepsilon\sqrt{D}} \tag{16}$$

$$D = c^2 + 1. \tag{17}$$

In the case of a solvable quintic, the roots can be found using the formulas of Malfatti (1771), who was the first to "solve" the quintic using a resolvent of sixth degree (Pierpont 1895).

The general quintic can be solved in terms of JACOBI THETA FUNCTIONS, as was first done by Hermite in 1858. Kronecker subsequently obtained the same solution more simply, and Brioshi also derived the equation. To do so, reduce the general quintic

$$a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 = 0 \tag{18}$$

into BRING QUINTIC FORM

$$x^5 - x + \rho = 0. \tag{19}$$

Then define

$$k \equiv \tan\left[\tfrac{1}{4}\sin^{-1}\left(\frac{16}{25\sqrt{5}\rho^2}\right)\right] \tag{20}$$

$$s \equiv \begin{cases} -\operatorname{sgn}(\Im[\rho]) & \text{for } \Re[\rho] = 0 \\ \operatorname{sgn}(\Re[\rho]) & \text{for } \Re[\rho] \neq 0 \end{cases} \tag{21}$$

$$b = \frac{s(k^2)^{1/8}}{2 \cdot 5^{3/4}\sqrt{k(1-k^2)}} \tag{22}$$

$$q = q(k^2) = e^{i\pi K'(k^2)/K(k^2)}, \tag{23}$$

where k is the MODULUS, $m \equiv k^2$ is the PARAMETER, and q is the NOME. Solving

$$q(m) = e^{i\pi K'(m)/K(m)} \tag{24}$$

for m gives the INVERSE NOME $m(q)$, and the roots of the original quintic are then given by

$$\begin{aligned} x_1 = (-1)^{3/4} b &\left\{\left[m\left(e^{-2\pi i/5}q^{1/5}\right)\right]^{1/8} + i\left[m\left(e^{2\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{\left[m\left(e^{-4\pi i/5}q^{1/5}\right)\right]^{1/8} + \left[m\left(e^{4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{\left[m\left(q^{1/5}\right)\right]^{1/8} + q^{5/8}\left(q^5\right)^{-1/8}\left[m\left(q^5\right)\right]^{1/8}\right\} \end{aligned} \tag{25}$$

$$\begin{aligned} x_2 = b &\left\{-\left[m\left(q^{1/5}\right)\right]^{1/8} + e^{3\pi i/4}\left[m\left(e^{2\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{e^{-3\pi i/4}\left[m\left(e^{-2\pi i/5}q^{1/5}\right)\right]^{1/8} + i\left[m\left(e^{4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{i\left[m\left(e^{-4\pi i/5}q^{1/5}\right)\right]^{1/8} + q^{5/8}\left(q^5\right)^{-1/8}\left[m\left(q^5\right)\right]^{1/8}\right\} \end{aligned} \tag{26}$$

$$\begin{aligned} x_3 = b &\left\{e^{-3\pi i/4}\left[m\left(e^{-2\pi i/5}q^{1/5}\right)\right]^{1/8} - i\left[m\left(e^{-4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{-\left[m\left(q^{1/5}\right)\right]^{1/8} - i\left[m\left(e^{4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{e^{-3\pi i/4}\left[m\left(e^{2\pi i/5}q^{1/5}\right)\right]^{1/8} + q^{5/8}\left(q^5\right)^{-1/8}\left[m\left(q^{1/5}\right)\right]^{1/8}\right\} \end{aligned} \tag{27}$$

$$\begin{aligned} x_4 = b &\left\{\left[m\left(q^{1/5}\right)\right]^{1/8} - i\left[m\left(e^{-4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \\ &\times\left\{-e^{-3\pi i/4}\left[m\left(e^{2\pi i/5}q^{1/5}\right)\right]^{1/8} - i\left[m\left(e^{4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\} \end{aligned}$$

$$\times\left\{e^{-3\pi i/4}\left[m\left(e^{-2\pi i/5}q^{1/5}\right)\right]^{1/8}+q^{5/8}\left(q^5\right)^{-1/8}\left[m\left(q^5\right)\right]^{1/8}\right\} \quad (28)$$

$$x_5=b\left\{\left[m\left(q^{1/5}\right)\right]^{1/8}-e^{-3\pi i/4}\left[m\left(e^{-2\pi i/5}q^{1/5}\right)\right]^{1/8}\right\}$$
$$\times\left\{-e^{3\pi i/4}\left[m\left(e^{2\pi i/5}q^{1/5}\right)\right]^{1/8}+i\left[m\left(e^{-4\pi i/5}q^{1/5}\right)\right]^{1/8}\right\}$$
$$\times\left\{\left(-i\left[m\left(e^{4\pi i/5}q^{1/5}\right)\right]^{1/8}+q^{5/8}\left(q^5\right)^{-1/8}\left[m\left(q^5\right)\right]^{1/8}\right\}. \quad (29)$$

Felix Klein used a TSCHIRNHAUSEN TRANSFORMATION to reduce the general quintic to the form

$$z^5+5az^2+5bz+c=0. \quad (30)$$

He then solved the related ICOSAHEDRAL EQUATION

$$I(z,1,Z)=z^5\left(-1+11z^5+z^{10}\right)^5$$
$$-\left[1+z^{30}-10005\left(z^{10}+z^{20}\right)+522\left(-z^5+z^{25}\right)\right]^2 Z$$
$$=0, \quad (31)$$

where Z is a function of radicals of a, b, and c. The solution of this equation can be given in terms of HYPERGEOMETRIC FUNCTIONS as

$$\frac{Z^{-1/60}\,{}_2F_1\left(-\frac{1}{60},\frac{29}{60},\frac{4}{5},1728Z\right)}{Z^{11/60}\,{}_2F_1\left(\frac{11}{60},\frac{41}{60},\frac{6}{5},1728Z\right)}. \quad (32)$$

Another possible approach uses a series expansion, which gives one root (the first one in the list below) of the BRING QUINTIC FORM

$$t^5-t-\rho. \quad (33)$$

All five roots can be derived using differential equations (Cockle 1860, Harley 1862). Let

$$F_1(\rho)=F_2(\rho) \quad (34)$$

$$F_2(\rho)={}_4F_3\left(\tfrac{1}{5},\tfrac{2}{5},\tfrac{3}{5},\tfrac{4}{5};\tfrac{1}{2},\tfrac{3}{4},\tfrac{5}{4};\tfrac{3125}{256}\rho^4\right) \quad (35)$$

$$F_3(\rho)={}_4F_3\left(\tfrac{9}{20},\tfrac{13}{20},\tfrac{17}{20},\tfrac{21}{20};\tfrac{3}{4},\tfrac{5}{4},\tfrac{3}{2};\tfrac{3125}{256}\rho^4\right) \quad (36)$$

$$F_4(\rho)={}_4F_3\left(\tfrac{7}{10},\tfrac{9}{10},\tfrac{11}{10},\tfrac{13}{10};\tfrac{5}{4},\tfrac{3}{2},\tfrac{7}{4};\tfrac{3125}{256}\rho^4\right), \quad (37)$$

then the ROOTS are

$$t_1=-\rho\,{}_4F_3\left(\tfrac{1}{5},\tfrac{2}{5},\tfrac{3}{5},\tfrac{4}{5};\tfrac{1}{2},\tfrac{3}{4},\tfrac{5}{4};\tfrac{3125}{256}\rho^4\right) \quad (38)$$

$$t_2=-F_1(\rho)+\tfrac{1}{4}\rho F_2(\rho)+\tfrac{5}{32}\rho^2F_3(\rho)+\tfrac{5}{32}\rho^3F_4(\rho) \quad (39)$$

$$t_3=-F_1(\rho)+\tfrac{1}{4}\rho F_2(\rho)-\tfrac{5}{32}\rho^2F_3(\rho)+\tfrac{5}{32}\rho^3F_4(\rho) \quad (40)$$

$$t_4=-iF_1(\rho)+\tfrac{1}{4}\rho F_2(\rho)-\tfrac{5}{32}i\rho^2F_3(\rho)-\tfrac{5}{32}\rho^3F_4(\rho) \quad (41)$$

$$t_5=-iF_1(\rho)+\tfrac{1}{4}\rho F_2(\rho)+\tfrac{5}{32}i\rho^2F_3(\rho)-\tfrac{5}{32}\rho^3F_4(\rho) \quad (42)$$

This technique gives closed form solutions in terms of HYPERGEOMETRIC FUNCTIONS in one variable for any POLYNOMIAL equation which can be written in the form

$$x^p+bx^q+c. \quad (43)$$

Consider the quintic

$$\prod_{j=0}^{4}\left[x-\left(\omega^j u_1+\omega^{4j}u_2\right)\right]=0, \quad (44)$$

where $\omega=e^{2\pi i/5}$ and u_1 and u_2 are COMPLEX NUMBERS. This is called DE MOIVRE'S QUINTIC. Generalize it to

$$\prod_{j=0}^{4}\left[x-\left(\omega^j u_1+\omega^{2j}u_2+\omega^{3j}u_3+\omega^{4j}u_4\right)\right]=0 \quad (45)$$

Expanding,

$$\left(\omega^j u_1+\omega^{2j}u_2+\omega^{3j}u_3+\omega^{4j}u_4\right)^5$$
$$-5U\left(\omega^j u_1+\omega^{2j}u_2+\omega^{3j}u_3+\omega^{4j}u_4\right)^4$$
$$-5V\left(\omega^j u_1+\omega^{2j}u_2+\omega^{3j}u_3+\omega^{4j}u_4\right)^2$$
$$+5W\left(\omega^j u_1+\omega^{2j}u_2+\omega^{3j}u_3+\omega^{4j}u_4\right)$$
$$+[5(X-Y)-Z]=0, \quad (46)$$

where

$$U=u_1u_4+u2u_3 \quad (47)$$

$$V=u_1u_2^2+u_2u_4^2+u_3u_1^2+u_4u_3^2 \quad (48)$$

$$W=u_1^2u_4^2+u_2^2u_3^2-u_1^3u_2-u_2^3u_4-u_3^3u_1-u_4^3u_3$$
$$-u_1u_2u_3u_4 \quad (49)$$

$$X=u_1^3u_3u_4+u_2^3u_1u_3+u_3^3u_2u_4+u_4^3u_1u_2 \quad (50)$$

$$Y=u_1u_3^2u_4^2+u_2u_1^2u_3^2+u_3u_2^2u_4^2+u_4u_1^2u_2^2 \quad (51)$$

$$Z=u_1^5+u_2^5+u_3^5+u_4^5 \quad (52)$$

The u_is satisfy

$$u_1u_4+u_2u_3=0 \quad (53)$$

$$u_1u_2^2+u_2u_4^2+u_3u_1^2+u_4u_3^2=0 \quad (54)$$

$$u_1^2u_4^2+u_2^2u_3^2-u_1^3u_2-u_2^3u_4-u_3^3u_1-u_4^3u_3-u_1u_2u_3u_4$$
$$=\tfrac{1}{5}a \quad (55)$$

$$5\left[\left(u_1^3u_3u_4+u_2^3u_1u_3+u_3^3u_3u_4+u_4^3u_1u_2\right)\right.$$
$$\left.-\left(u_1u_3^2u_4^2+u_2u_1^2u_3^2+u_3u_2^2u_4^2+u_4u_1^2u_2^2\right)\right]$$
$$-\left(u_1^5+u_2^5+u_3^5+u_4^5\right)=b. \quad (56)$$

Quintic Graph

A quintic graph is a GRAPH which is 5-REGULAR. The only quintic graph on $n \leq 7$ nodes is the COMPLETE GRAPH K_6. The following tables gives polyhedra whose SKELETONS are quartic.

POLYHEDRON	nodes
ICOSAHEDRON	12
SNUB CUBE	24
SNUB DODECAHEDRON	60
TRUNCATED DODECAHEDRON	60

See also CUBIC GRAPH, QUARTIC GRAPH, REGULAR GRAPH

Quintic Surface

A quintic surface is an ALGEBRAIC SURFACE of degree 5. Togliatti (1940, 1949) showed that quintic surfaces having 31 ORDINARY DOUBLE POINTS exist, although he did not explicitly derive equations for such surfaces. Beauville (1978) subsequently proved that 31 double points was the maximum possible, and quintic surfaces having 31 ORDINARY DOUBLE POINTS are therefore sometimes called TOGLIATTI SURFACES. van Straten (1993) subsequently constructed a 3-D family of solutions and in 1994, Barth derived the example known as the DERVISH.

Quintillion

In the American system, 10^{18}.

See also LARGE NUMBER

Quintuple

A group of five elements, also called a QUINTUPLET or PENTAD.

See also MONAD, PAIR, PENTAD, QUADRUPLE, QUADRUPLET, QUINTUPLET, TETRAD, TRIAD, TRIPLET, TWINS

Quintuple Product Identity

A.k.a. the WATSON QUINTUPLE PRODUCT IDENTITY,

$$\prod_{n=1}^{\infty}(1-q^n)(1-zq^n)\left(1-z^{-1}q^{n-1}\right)\left(1-z^2q^{2n-1}\right)$$

$$\times\left(1-z^{-2}q^{2n-1}\right)=\sum_{m=-\infty}^{\infty}\left(z^{3m}-z^{-3m-1}\right)q^{m(2m+1)/2}. \quad (1)$$

It can also be written

$$\prod_{n=1}^{\infty}\left(1-q^{2n}\right)\left(1-q^{2n-1}z\right)\left(1-q^{2n-1}z^{-1}\right)\left(1-q^{4n-3}z^2\right)$$

$$\times\left(1-q^{4n-4}z^{-2}\right)$$

$$=\sum_{n=-\infty}^{\infty}q^{3n^2-2n}\left[\left(z^{3n}+z^{-3n}\right)-\left(z^{3n-2}+z^{-(3n-2)}\right)\right] \quad (2)$$

or

$$\sum_{k=-\infty}^{\infty}(-1)^k q^{\left(3k^2-k\right)/2}x^{3k}\left(1+zq^k\right)$$

$$=\prod_{j=1}^{\infty}\left(1-q^j\right)\left(1+z^{-1}q^j\right)\left(1+zq^{j-1}\right)\left(1+z^{-2}q^{2j-1}\right)$$

$$\times\left(1+z^2q^{2j-1}\right). \quad (3)$$

The quintuple product identity can be written in q-SERIES notation as

$$\sum_{k=-\infty}^{\infty}(-1)^k q^{k(3k-1)/2}z^{3k}\left(1+zq^k\right)$$

$$=(1,-z,-q/z;q)_{\infty}\left(qz^2,q/z^2;q^2\right)_{\infty}, \quad (4)$$

where $0<|q|<1$ and $z\neq 0$ (Gasper and Rahman 1990, p. 134; Leininger and Milne 1997). Using the NOTATION of the RAMANUJAN THETA FUNCTION (Berndt, p. 83),

$$f\left(B^3/q,q^5/B^3\right)-B^2f\left(q/B^3,B^3q^5\right)$$

$$=f\left(-q^2\right)\frac{f\left(-B^2,-q^2/B^2\right)}{f(Bq,q/B)} \quad (5)$$

See also JACOBI TRIPLE PRODUCT, RAMANUJAN THETA FUNCTIONS

Quiteprime

A POSITIVE INTEGER $n>1$ is quiteprime IFF all PRIMES $p\leq\sqrt{n}$ satisfy

$$|2[n \pmod p]-p|\leq p+1-\sqrt{p}.$$

Also define 2 and 3 to be quiteprimes. Then the first few quiteprimes are 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, 137, ... (Sloane's A050260), and the first few primes which are *not* quiteprimes are 131, 181, 197, 199, 233, 241, 263, 307, 311, 313, 331, 337, 353, 373, 379, ... (Sloane's A050261).

Quota Rule

A RECURRENCE RELATION between the function Q arising in QUOTA SYSTEMS,

$$Q(n,r) = Q(n-1,r-1) + Q(n-1,r).$$

References

Young, S. C.; Taylor, A. D.; and Zwicker, W. S. "Counting Quota Systems: A Combinatorial Question from Social Choice Theory." *Math. Mag.* **68**, 331–342, 1995.

Quota System

A generalization of simple majority voting in which a list of quotas $\{q_0, \ldots, q_n\}$ specifies, according to the number of votes, how many votes an alternative needs to win (Taylor 1995). The quota system declares a tie unless for some k, there are exactly k tie votes in the profile and one of the alternatives has at least q_k votes, in which case the alternative is the choice.

Let $Q(n)$ be the number of quota systems for n voters and $Q(n,r)$ the number of quota systems for which $q_0 = r+1$, so

$$Q(n) = \sum_{r=\lfloor n/2 \rfloor}^{n} Q(n,r) = \binom{n+1}{\left\lfloor \frac{n}{2} \right\rfloor + 1},$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION. This produces the sequence of CENTRAL BINOMIAL COEFFICIENTS 1, 2, 3, 6, 10, 20, 35, 70, 126, ... (Sloane's A001405). It may be defined recursively by $Q(0) = 1$ and

$$Q(n+1) = \begin{cases} 2Q(n) & \text{for } n \text{ even} \\ 2Q(n) - C_{(n+1)/2} & \text{for } n \text{ odd,} \end{cases}$$

where C_k is a CATALAN NUMBER (Young *et al.* 1995). The function $Q(n,r)$ satisfies

$$Q(n,r) = \binom{n+1}{r+1} - \binom{n+1}{r+2}$$

for $r > n/2 - 1$ (Young *et al.* 1995). $Q(n,r)$ satisfies the QUOTA RULE.

Quotient

The ratio $q = r/s$ of two quantities r and s, where $s \neq 0$. Less commonly, the term quotient is also used to mean the INTEGER PART of such a ratio. In *Mathematica*, the command `Quotient[r, s]` is defined in this latter sense, returning $\lfloor r/s \rfloor$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

See also Division, Fraction, Integer Part, Quotient Group, Quotient Ring, Quotient Space, Rational Number, Remainder

Quotient Group

For a GROUP G and a NORMAL SUBGROUP N of G, the quotient group of N in G, written G/N and read "G modulo N", is the set of COSETS of N in G. Quotient groups are also called factor groups. The elements of G/N are written Na and form a GROUP under the normal operation on the group N on the coefficient a. Thus,

$$(Na)(Nb) = Nab.$$

Since all elements of G will appear in exactly one COSET of the NORMAL SUBGROUP N, it follows that

$$|G/N| = |G|/|N|$$

where $|G|$ denotes the order of a group.

The slash NOTATION conflicts with that for an EXTENSION FIELD, but the meaning can be determined based on context.

Quotient Ring

A quotient ring (also called a residue-class ring) is a RING which is the quotient of a RING A and one of its IDEALS $\mathfrak{a}$, denoted $A/\mathfrak{a}$. For example, when the RING A is $\mathbb{Z}$ (the integers) and the IDEAL is $6\mathbb{Z}$ (multiples of 6), the quotient ring is $\mathbb{Z}_6 = \mathbb{Z}/6\mathbb{Z}$.

In general, a quotient ring is a set of EQUIVALENCE CLASSES where $[x] = [y]$ IFF $x - y \in \mathfrak{a}$.

The quotient ring is an INTEGRAL DOMAIN iff the IDEAL $\mathfrak{a}$ is PRIME. A stronger condition occurs when the quotient ring is a FIELD, which corresponds to when the ideal $\mathfrak{a}$ is MAXIMAL.

The IDEALS in a quotient ring $A/\mathfrak{a}$ are in a ONE-TO-ONE correspondence with ideals in A which contain the ideal $\mathfrak{a}$. In particular, the zero ideal in $A/\mathfrak{a}$ corresponds to $\mathfrak{a}$ in A. In the example above from the integers, the ideal of even integers contains the ideal of the multiples of 6. In the quotient ring, the evens correspond to the ideal $\{0, 2, 4\}$ in $\mathbb{Z}_6 = \mathbb{Z}/6\mathbb{Z}$.

See also Field, Ideal, Integer, Integral Domain, Maximal Ideal, Module, Prime Ideal, Residue Field, Ring

Quotient Rule

The DERIVATIVE rule

$$\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] = \frac{g(x)f'(x) - f(x)g'(x)}{[g(x)]^2}$$

See also CHAIN RULE, DERIVATIVE, POWER RULE, PRODUCT RULE

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, p. 11, 1972.

Quotient Space

The quotient space $X/\sim$ of a TOPOLOGICAL SPACE X and an EQUIVALENCE RELATION $\sim$ on X is the set of EQUIVALENCE CLASSES of points in X (under the EQUIVALENCE RELATION $\sim$) together with the following topology given to subsets of $X/\sim$: a subset U of $X/\sim$ is called open IFF $\cup_{[a]\in U} a$ is open in X. Quotient spaces are also called factor spaces.

This can be stated in terms of MAPS as follows: if $q : X \to X/\sim$ denotes the MAP that sends each point to its EQUIVALENCE CLASS in $X/\sim$, the topology on $X/\sim$ can be specified by prescribing that a subset of $X/\sim$ is open IFF q^{-1} [the set] is open.

In general, quotient spaces are not well behaved, and little is known about them. However, it is known that any compact metrizable space is a quotient of the CANTOR SET, any compact connected n-dimensional MANIFOLD for $n > 0$ is a quotient of any other, and a function out of a quotient space $f : X/\sim \to Y$ is continuous IFF the function $f \circ q : X \to Y$ is continuous.

Let $\mathbb{D}^n$ be the closed n-D DISK and $\mathbb{S}^{n-1}$ its boundary, the $(n-1)$-D sphere. Then $\mathbb{D}^n/\mathbb{S}^{n-1}$ (which is homeomorphic to $\mathbb{S}^n$), provides an example of a quotient space. Here, $\mathbb{D}^n/\mathbb{S}^{n-1}$ is interpreted as the space obtained when the boundary of the n-DISK is collapsed to a point, and is formally the "quotient space by the equivalence relation generated by the relations that all points in $\mathbb{S}^{n-1}$ are equivalent."

See also EQUIVALENCE RELATION, QUOTIENT SPACE (LIE GROUP), TOPOLOGICAL SPACE

References

Munkres, J. R. *Topology: A First Course.* Englewood Cliffs, NJ: Prentice-Hall, 1975.

Quotient Space (Lie Group)

The set of LEFT COSETS of a SUBGROUP H of a TOPOLOGICAL GROUP G forms a topological space. Its topology is defined by the quotient topology from $\pi : G \to G/H$. Namely, the open sets in G/H are the images of the open sets in G. Moreover, if H is CLOSED, then G/H is HAUSDORFF.

See also EFFECTIVE ACTION, FREE ACTION, GEOMETRIC INVARIANT THEORY, GROUP, ISOTROPY GROUP, MATRIX GROUP, ORBIT (GROUP), QUOTIENT SPACE, REPRESENTATION, TOPOLOGICAL GROUP, TRANSITIVE

References

Kawakubo, K. *The Theory of Transformation Groups.* Oxford, England: Oxford University Press, pp. 7–14 and 41–49, 1987.

Quotient Vector Space

Suppose that $V = \{(x_1, x_2, x_3)\}$ and $W = \{(x_1, 0, 0)\}$. Then the quotient space V/W (read as "V mod W") is isomorphic to $\{(x_2, x_3)\} = \mathbb{R}^2$.

In general, when W is a SUBSPACE of a VECTOR SPACE V, the quotient space V/W is the set of EQUIVALENCE CLASSES $[v]$ where $v_1 \sim v_2$ if $v_1 - v_2 \in W$. By "v_1 is equivalent to v_2 modulo W," it is meant that $v_1 = v_2 + w$ for some w in W, and is another way to say $v_1 \sim v_2$. In particular, the elements of W represent $[0]$. Sometimes the equivalence classes $[v]$ are written as COSETS $v + W$.

The quotient space is an ABSTRACT VECTOR SPACE, not necessarily isomorphic to a subspace of V. However, if V has an INNER PRODUCT, then V/W is isomorphic to

$$W^\perp = \{v : \langle v, w\rangle = 0 \text{ for all } w \in W\}.$$

In the example above, $W^\perp = \{(0, x_2 x_3)\}$. Here is a *Mathematica* function which finds a basis to $W^\perp$ when given a basis for W.

```
PerpVectorBasis[a_List?MatrixQ]                :=
NullSpace[a]
```

For example, `PerpVectorBasis`[{{1, 2, 0, 0, 3}, {4, 0, 5, 0, 6}}] yields {{-6, -3, 0, 0, 4}, {0, 0, 0, 1, 0}, {-10, 5, 8, 0, 0}}.

Unfortunately, a different choice of inner product can change $W^\perp$. Also, in the infinite-dimensional case, it is necessary for W to be a CLOSED SUBSPACE to realize the isomorphism between V/W and $W^\perp$, as well as to ensure the quotient space is HAUSDORFF.

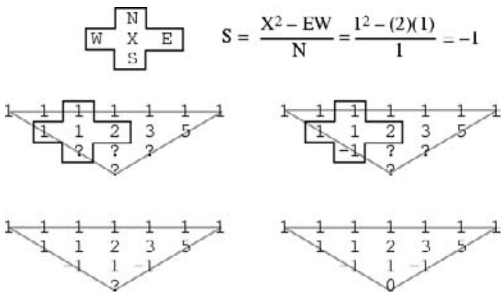
Quotient-Difference Algorithm



The ALGORITHM of constructing and interpreting a QUOTIENT-DIFFERENCE TABLE which allows interconversion of CONTINUED FRACTIONS, POWER SERIES, and RATIONAL FUNCTIONS approximations.

See also QUOTIENT-DIFFERENCE TABLE

References

Sloane, N. J. A. and Plouffe, S. *The Encyclopedia of Integer Sequences.* San Diego, CA: Academic Press, pp. 15–17, 1995.

Quotient-Difference Table

A quotient-difference table is a triangular ARRAY of numbers constructed by drawing a sequence of n numbers in a horizontal row and placing a 1 above each. An additional "1" is then placed at the beginning and end of the row of 1s, and the value of rows underneath the original row is then determined by looking at groups of adjacent numbers

$$\begin{array}{ccc} & N & \\ W & X & E \\ & S & \end{array}$$

and computing

$$S = \frac{X^2 - EW}{N}$$

for the elements falling within a triangle formed by the diagonals extended from the first and last "1," as illustrated above.

0s in quotient-difference tables form square "windows" which are bordered by GEOMETRIC SEQUENCES. Quotient-difference tables eventually yield a row of 0s IFF the starting sequence is defined by a linear RECURRENCE RELATION. For example, continuing the above example generated by the FIBONACCI NUMBERS

$$\begin{array}{ccccccc} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ & 1 & 1 & 2 & 3 & 5 & \\ & & -1 & 1 & -1 & & \\ & & & 0 & & & \end{array}$$

$$\begin{array}{cccccccc} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ & 1 & 1 & 2 & 3 & 5 & 8 & \\ & & -1 & 1 & -1 & 1 & & \\ & & & 0 & 0 & & & \end{array}$$

$$\begin{array}{ccccccccc} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ & 1 & 1 & 2 & 3 & 5 & 8 & 13 & \\ & & -1 & 1 & -1 & 1 & -1 & & \\ & & & 0 & 0 & 0 & & & \\ & & & & 0 & & & & \end{array}$$

$$\begin{array}{cccccccccc} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ & 1 & 1 & 2 & 3 & 5 & 8 & 13 & 21 & \\ & & -1 & 1 & -1 & 1 & -1 & 1 & & \\ & & & 0 & 0 & 0 & 0 & & & \\ & & & & 0 & 0 & & & & \end{array}$$

and it can be seen that a row of 0s emerges (and furthermore that an attempt to extend the table will result in division by zero). This verifies that the FIBONACCI NUMBERS satisfy a linear recurrence, which is in fact given by the well-known formula

$$F_n = F_{n-1} + F_{n-2}.$$

However, construction of a quotient-difference table for the CATALAN NUMBERS, MOTZKIN NUMBERS, etc., does not lead to a row of zeros, suggesting that these numbers cannot be generated using a linear recurrence.

Raabe's Test

Given a SERIES of POSITIVE terms u_i and a SEQUENCE of POSITIVE constants $\{a_i\}$, use KUMMER'S TEST

$$\rho' \equiv \lim_{n\to\infty}\left(a_n \frac{u_n}{u_{n+1}} - a_{n+1}\right)$$

with $a_n = n$, giving

$$\rho' \equiv \lim_{n\to\infty}\left[n \frac{u_n}{u_{n+1}} - (n+1)\right]$$

$$= \lim_{n\to\infty}\left[n\left(\frac{u_n}{u_{n+1}} - 1\right) - 1\right].$$

Defining

$$\rho \equiv \rho' + 1 = \lim_{n\to\infty}\left[n\left(\frac{u_n}{u_{n+1}} - 1\right)\right],$$

then gives Raabe's test:

1. If $\rho > 1$, the SERIES CONVERGES.
2. If $\rho < 1$, the SERIES DIVERGES.
3. If $\rho = 1$, the SERIES may CONVERGE or DIVERGE.

Rabbit Constant

The limiting RABBIT SEQUENCE written as a BINARY FRACTION $0.1011010110110\ldots_2$ (Sloane's A005614), where b_2 denotes a BINARY number (a number in base-2). The DECIMAL value is

$$R = 0.709803442861291314\ldots$$

(Sloane's A014565).

Amazingly, the rabbit constant is also given by the CONTINUED FRACTION $[0, 2^{F_0}, 2^{F_1}, 2^{F_2}, 2^{F_3}, \ldots]$, where F_n are FIBONACCI NUMBERS with F_0 taken as 0 (Gardner 1989, Schroeder 1991). Another amazing connection was discovered by S. Plouffe. Define the BEATTY SEQUENCE $\{a_i\}$ by

$$a_i \equiv \lfloor i\phi \rfloor$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and ϕ is the GOLDEN RATIO. The first few terms are 1, 3, 4, 6, 8, 9, 11, ... (Sloane's A000201). Then

$$R = \sum_{i=1}^{\infty} 2^{-a_i}$$

Rabbit Sequence

A SEQUENCE which arises in the hypothetical reproduction of a population of rabbits. Let the SUBSTITUTION MAP $0 \to 1$ correspond to young rabbits growing old, and $1 \to 10$ correspond to old rabbits producing young rabbits. Starting with 0 and iterating using STRING REWRITING gives the terms 1, 10, 101, 10110, 10110101, 1011010110110, ... Converted to binary, this sequence gives 1, 2, 5, 22, 181, ... (Sloane's A005203), with the nth term given by the RECUR-

rence relation

$$a(n) = a(n-1)2^{F_{n-1}} + a(n-2),$$

with $a(0) = 0$, $a(1) = 1$, and F_n the nth Fibonacci number.

The limiting sequence written as a binary fraction $0.1011010110110\ldots_2$ (Sloane's A005614), where $(a_n \ldots a_1 a_0)_2$ denotes a binary number (i.e., a number written in base 2, so $a_i = 0$ or 1), is called the rabbit constant.

Rabdology

Napier's Bones

Rabin-Miller Strong Pseudoprime Test

A primality test which provides an efficient probabilistic algorithm for determining if a given number is prime. It is based on the properties of strong pseudoprimes. Given an odd integer n, let $n = 2^r s + 1$ with s odd. Then choose a random integer a with $1 \leq a \leq n-1$. If $a^s \equiv 1 \pmod{n}$ or $a^{2^j s} \equiv -1 \pmod{n}$ for some $0 \leq j \leq r-1$, then n passes the test. A prime will pass the test for all a.

The test is very fast and requires no more than $(1 + o(1)) \lg n$ multiplications (mod n), where lg is the logarithm base 2. Unfortunately, a number which passes the test is not necessarily prime. Monier (1980) and Rabin (1980) have shown that a composite number passes the test for at most 1/4 of the possible bases a.

The Rabin-Miller test (combined with a Lucas pseudoprime test) is the primality test used by *Mathematica* versions 2.2 and later. As of 1991, the combined test had been proven correct for all $n < 2.5 \times 10^{10}$, but not beyond. The test potentially could therefore incorrectly identify a large composite number as prime (but not vice versa). Strong pseudoprime tests have been subsequently proved valid for every number up to 3.4×10^{14}.

Racah 6j-Symbol

Wigner 6j-Symbol

Racah Polynomial

A hypergeometric class of orthogonal polynomials defined by

$$R_n(\lambda(x);\ \alpha,\ \beta,\ \gamma,\ \delta)$$

$$= {}_4F_3\left(\begin{matrix}-n,\ n+\alpha+\beta+1,\ -x,\ x+\gamma+\delta+1\\ \alpha+1,\ \beta+\delta+1,\ \gamma+1\end{matrix};\ 1\right)$$

for $n = 0, 1, ..., N$, where ${}_4F_3(a, b, c, d;\ e, f, g;\ x)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION,

$$\lambda(x) = x(x+\gamma+\delta+1),$$

and one of the following holds

$$\begin{cases}\alpha+1=-N\\ \beta+\delta+1=-N\\ \gamma+1=-N,\end{cases}$$

with N a NONNEGATIVE INTEGER.

Radau Quadrature

A GAUSSIAN QUADRATURE-like formula for numerical estimation of integrals. It requires $m+1$ points and fits all POLYNOMIALS to degree $2m$, so it effectively fits exactly all POLYNOMIALS of degree $2m-1$. It uses a WEIGHTING FUNCTION $W(x)=1$ in which the endpoint -1 in the interval $[-1,\ 1]$ is included in a total of n ABSCISSAS, giving $r=n-1$ free abscissas. The general formula is

$$\int_{-1}^{1} f(x)\,dx = w_1f(-1) + \sum_{i=2}^{n} w_if(x_i). \tag{1}$$

The free abscissas x_i for $i=2, ..., n$ are the roots of the POLYNOMIAL

$$\frac{P_{n-1}(x)+P_n(x)}{1+x}, \tag{2}$$

where $P(x)$ is a LEGENDRE POLYNOMIAL. The weights of the free abscissas are

$$w_i = \frac{1-x_i}{n^2[P_{n-1}(x_i)]^2} = \frac{1}{(1-x_i)[P'_{n-1}(x_i)]^2}, \tag{3}$$

and of the endpoint

$$w_1 = \frac{2}{n^2}. \tag{4}$$

The error term is given by

$$E = \frac{2^{2n-1}n[(n-1)!]^4}{[(2n-1)!]^3}\,f^{(2n-1)}(\xi), \tag{5}$$

for $\xi \in (-1,\ 1)$.

n	x_i	w_i
2	-1	0.5
	0.333333	1.5
3	-1	0.222222
	−0.289898	1.02497
	0.689898	0.752806
4	-1	0.125
	−0.575319	0.657689
	0.181066	0.776387
	0.822824	0.440924
5	-1	0.08
	−0.72148	0.446208
	−0.167181	0.623653
	0.446314	0.562712
	0.885792	0.287427

The ABSCISSAS and weights can be computed analytically for small n.

n	x_i	w_i
2	-1	$\frac{1}{2}$
	$\frac{1}{3}$	$\frac{3}{2}$
3	-1	$\frac{2}{9}$
	$\frac{1}{5}(1-\sqrt{6})$	$\frac{1}{18}(16+\sqrt{6})$
	$\frac{1}{5}(1+\sqrt{6})$	$\frac{1}{18}(16-\sqrt{6})$

Rademacher Function

SQUARE WAVE

Radial Curve

Let C be a curve and let O be a fixed point. Let P be on C and let Q be the CURVATURE CENTER at P. Let P_1 be the point with P_1O a line segment PARALLEL and of equal length to PQ. Then the curve traced by P_1 is the radial curve of C. It was studied by Robert Tucker in 1864. The PARAMETRIC EQUATIONS of a curve $(f(t),\ g(t))$ with RADIAL POINT $(x_0,\ y_0)$ and parameterized by a variable t are given by

$$x = x_0 - \frac{g'(f'^2 + g'^2)}{f'g'' - f''g'}$$

$$y = y_0 + \frac{f'(f'^2 + g'^2)}{f'g'' - f''g'}.$$

Here, derivatives are taken with respect to the parameter t.

Radial Point

The point with respect to which a RADIAL CURVE is computed.

See also RADIANT POINT

Radian

A unit of angular measure in which the ANGLE of an entire CIRCLE is 2π radians. There are therefore 360° per 2π radians, equal to $180°/\pi$ or 57. 29577951°/ radian. A RIGHT ANGLE is $\pi/2$ radians.

See also ANGLE, ARC MINUTE, ARC SECOND, DEGREE, GRADIAN, STERADIAN

Radiant Point

The point of illumination for a CAUSTIC.

See also CAUSTIC, RADIAL POINT

Radical

The symbol $\sqrt{x}$ used to indicate a root is called a radical. The expression $\sqrt{x}$ is therefore read "x radical n," or "the nth ROOT of x." In the radical symbol, the horizonal line is called the VINCULUM, the quantity under the VINCULUM is called the RADICAND, and the quantity n written to the left is called the INDEX.

The special case $\sqrt{x}$ is written $\sqrt{x}$ and is called the SQUARE ROOT of x. $\sqrt[3]{x}$ is called the CUBE ROOT.

Some interesting radical identities are due to Ramanujan, and include the equivalent forms

$$(2^{1/3}+1)(2^{1/3}-1)^{1/3}=3^{1/3}$$

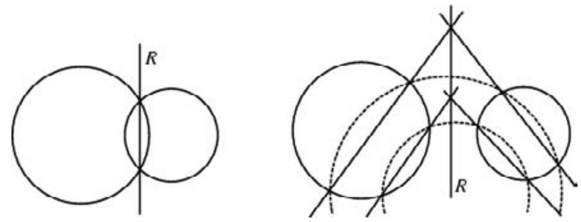
and

$$(2^{1/3}-1)^{1/3}=\left(\tfrac{1}{9}\right)^{1/3}-\left(\tfrac{2}{9}\right)^{1/3}+\left(\tfrac{4}{9}\right)^{1/3}.$$

Another such identity is

$$(5^{1/3}-4^{1/3})^{1/2}=\tfrac{1}{3}(2^{1/3}+20^{1/3}-25^{1/3}).$$

See also CUBE ROOT, INDEX, NESTED RADICAL, POWER, RADICAL INTEGER, RADICAND, ROOT (RADICAL), SQUARE ROOT, SURD, VINCULUM



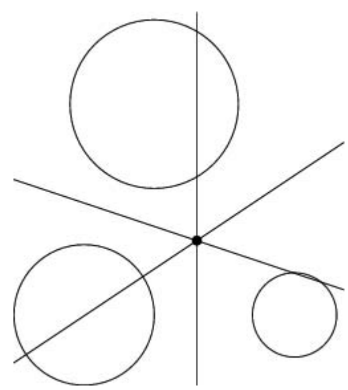
Radical (Ideal)

The radical of an IDEAL $r(\mathfrak{a})$ in a RING R is the ideal which is the intersection of all PRIME IDEALS containing $r(\mathfrak{a})$. Note that any ideal is contained in a MAXIMAL IDEAL, which is always prime. So the radical of an ideal is always at least as big as the original ideal. Naturally, if the ideal $r(\mathfrak{a})$ is prime then $r(\mathfrak{a})=\{x : x^n \in \mathfrak{a} \text{ for some integer } n>0\}$.

Another description of the radical $\mathbb{C}[x]$ is

$$\mathfrak{a}=\langle x^2\rangle$$

This explains the connection with the RADICAL symbol. For example, in $r(\mathfrak{a})=\langle x\rangle$, consider the ideal $\mathbb{C}$ of all polynomials with degree at least 2. Then $\sqrt[3]{7}+\sqrt{-2}-\sqrt{3+\sqrt[4]{1+\sqrt{2}}}$ is like a square root of $r(\mathfrak{a})$. Notice that the zero set (VARIETY) of $r(\mathfrak{a})$ and $\mathbb{C}[x]$ is the same (in $r(\mathfrak{a})=\langle x\rangle$ because



is ALGEBRAICALLY CLOSED). Radicals are an important part of the statement of the NULLSTELLENSATZ.

See also ALGEBRAIC GEOMETRY, IDEAL, JACOBSON RADICAL, NILRADICAL, NULLSTELLENSATZ, PRIME IDEAL, VARIETY

Radical Axis

RADICAL LINE

Radical Center

The RADICAL LINES of three CIRCLES are CONCURRENT in a point known as the radical center (also called the power center). This theorem was originally demonstrated by Monge (Dörrie 1965, p. 153). It is a special case of the THREE CONICS THEOREM (Evelyn *et al.* 1974, pp. 13 and 15).

See also APOLLONIUS' PROBLEM, CONCURRENT, MONGE'S PROBLEM, RADICAL LINE, THREE CONICS THEOREM

Radical Circle

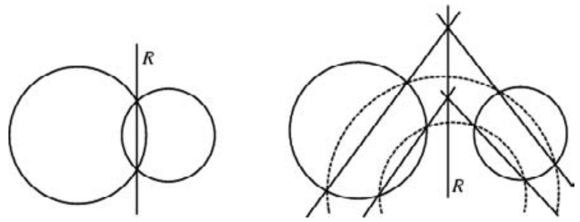
ORTHOGONAL CIRCLES

Radical Denesting

NESTED RADICAL

Radical Integer

A radical integer is a number obtained by closing the INTEGERS under ADDITION, MULTIPLICATION, SUBTRACTION, and ROOT EXTRACTION. An example of such a number is $\sqrt[3]{7}+\sqrt{-2}-\sqrt{3+\sqrt[4]{1+\sqrt{2}}}$. The radical integers are a SUBRING of the ALGEBRAIC INTEGERS.



There exist cubic ALGEBRAIC INTEGERS which are not radical integers, namely those which can't be expressed in terms of radicals. R. Schroeppel proved that these are the only ones; i.e., if an ALGEBRAIC INTEGER can be expressed in terms of radicals, then it can be done so *without using division.*

See also ALGEBRAIC INTEGER, ALGEBRAIC NUMBER, EUCLIDEAN NUMBER

References

Schroeppel, R. "radical & algebraic integers." math-fun@cs.arizona.edu posting, May 11, 1997.

Radical Line

The LOCUS of points of equal POWER with respect to two nonconcentric CIRCLES which is PERPENDICULAR to the line of centers (the CHORDAL THEOREM; Dörrie 1965). Let the circles have RADII r_1 and r_2 and their centers be separated by a distance d. If the CIRCLES intersect in two points, then the radical line is the line passing through the points of intersection. If not, then draw any two CIRCLES which cut each original CIRCLE twice. Draw lines through each pair of points of intersection of each CIRCLE. The line connecting their two points of intersection is then the radical line. The radical line is located at distances

$$d_1=\frac{d^2+r_1^2-r_2^2}{2d} \tag{1}$$

$$d_2=-\frac{d^2+r_2^2-r_1^2}{2d} \tag{2}$$

along the line of centers from C_1 and C_2, respectively, where

$$d \equiv d_1-d_2. \tag{3}$$

The radical line of any two POLAR CIRCLES is the ALTITUDE from the third vertex.

Radicand

The quantity under a RADICAL sign.

See also CUBE ROOT, RADICAL, ROOT, SQUARE ROOT, VINCULUM

Radius

The distance from the center of a CIRCLE to its

PERIMETER, or from the center of a SPHERE to its surface. The radius is equal to half the DIAMETER.

See also BERTRAND'S PROBLEM, CIRCLE, CIRCUMFERENCE, DIAMETER, EXTENT, GRAPH RADIUS, INVERSION RADIUS, KINNEY'S SET, PI, RADIUS OF CONVERGENCE, RADIUS OF CURVATURE, RADIUS OF GYRATION, RADIUS OF TORSION, RADIUS VECTOR, SPHERE

Radius of Convergence

A POWER SERIES $\Sigma^{\infty} c_k x^k$ will converge only for certain values of x. For instance, $\Sigma_{k=0}^{\infty} x^k$ converges for $-1 < x < 1$. In general, there is always an interval $(-R, R)$ in which a POWER SERIES converges, and the number R is called the radius of convergence. The quantity R is called the radius of convergence because, in the case of a power series with complex coefficients, the values of x with $|x| < R$ form an OPEN DISK with radius R.

A POWER SERIES always CONVERGES ABSOLUTELY within its radius of convergence. This can be seen by fixing $r = |x|$ and supposing that there exists a SUBSEQUENCE c_{n_i} such that $|c_{n_i}| r^{n_i}$ is UNBOUNDED. Then the POWER SERIES $\Sigma c_n x^n$ does not CONVERGE (in fact, the terms are unbounded) because it fails the LIMIT TEST. Therefore, for x with $r = |x| > R$, the power series does not converge, where

$$c = \limsup c_n \tag{1}$$

$$R = \frac{1}{c}, \tag{2}$$

and lim sup denotes the SUPREMUM LIMIT.

Conversely, suppose that $r < R$. Then for any radius s with $r < s < R$, the terms $c_n x^n$ satisfy

$$|c_n x^n| < \left(\frac{s}{R}\right)^n \tag{3}$$

for n large enough (depending on s). It is sufficient to fix a value for s in between r and R. Because $s/R < 1$, the power series is dominated by a convergent GEOMETRIC SERIES. Hence, the POWER SERIES converges absolutely by the LIMIT COMPARISON TEST.

Radius of Curvature

The radius of curvature is given by

$$R \equiv \frac{1}{\kappa}, \tag{1}$$

where κ is the CURVATURE. At a given point on a curve, R is the radius of the OSCULATING CIRCLE. The symbol ρ is sometimes used instead of R to denote the radius of curvature.

Let x and y be given parametrically by

$$x = x(t) \tag{2}$$

$$y = y(t), \tag{3}$$

then

$$R = \frac{(x'^2 + y'^2)^{3/2}}{x'y'' - y'x''}, \tag{4}$$

where $x' = dx/dt$ and $y' = dy/dt$. Similarly, if the curve is written in the form $y = f(x)$, then the radius of curvature is given by

$$R = \frac{\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}}{\frac{d^2y}{dx^2}}. \tag{5}$$

In POLAR COORDINATES $r = r(\theta)$, the radius of curvature is given by

$$R = \frac{(r^2 + r_\theta^2)^{3/2}}{r^2 + 2r_\theta^2 - rr_{\theta\theta}}, \tag{6}$$

where $r_\theta = dr/d\theta$ (Gray 1997, p. 89).

Radius of Gyration

A positive number k such that a lamina or solid body with moment of inertia about an axis I and mass m is given by

$$I = mk^2.$$

Pickover (1995) defines a generalization of k as a function R_g quantifying the spatial extent of the structure of a curve and given by

$$R_g = \frac{\sqrt{\int_0^\infty r^2 p(r)\,dr}}{2\int_0^\infty p(r)\,dr},$$

where $p(r)$ is the LENGTH DISTRIBUTION FUNCTION. Small compact patterns have small R_g.

See also RADIUS OF CURVATURE, RADIUS OF TORSION

References

Pickover, C. A. *Keys to Infinity.* New York: Wiley, pp. 204–206, 1995.

Radius of Torsion

$$\sigma \equiv \frac{1}{\tau},$$

where τ is the TORSION. The symbol ϕ is also sometimes used instead of σ.

See also RADIUS OF CURVATURE, TORSION (DIFFERENTIAL GEOMETRY)

References

Kreyszig, E. *Differential Geometry.* New York: Dover, p. 39, 1991.

Radius Vector

The VECTOR **r** from the ORIGIN to the current position. It is also called the position vector. The derivative of **r** satisfies

$$\mathbf{r}\cdot\frac{d\mathbf{r}}{dt} = \frac{1}{2}\frac{d}{dt}(\mathbf{r}\cdot\mathbf{r}) = \frac{1}{2}\frac{d}{dt}(r^2) = r\frac{dr}{dt} = rv,$$

where v is the magnitude of the VELOCITY (i.e., the SPEED).

See also RADIUS, SPEED, VELOCITY

Radix

The BASE of a number system, i.e., 2 for BINARY, 8 for OCTAL, 10 for DECIMAL, and 16 for HEXADECIMAL. The radix is sometimes called the BASE or SCALE.

See also BASE (NUMBER)

Radon Measure

See also PROBABILITY MEASURE

Radon Transform

An INTEGRAL TRANSFORM whose inverse is used to reconstruct images from medical CT scans. A technique for using Radon transforms to reconstruct a map of a planet's polar regions using a spacecraft in a polar orbit has also been devised (Roulston and Muhleman 1997).

The Radon transform can be defined by

$$R(p,\ \tau)[f(x,\ y)] = \int_{-\infty}^{\infty} f(x,\ \tau+px)\,dx$$

$$= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,\ y)\delta[y-(\tau+px)]\,dy\,dx \equiv U(p,\ \tau), \quad (1)$$

where p is the SLOPE of a line and τ is its intercept. The inverse Radon transform is

$$f(x,\ y) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{d}{dy}H[U(p,\ y-px)]\,dp, \quad (2)$$

where H is a HILBERT TRANSFORM. The transform can also be defined by

$$R'(r,\ \alpha)[f(x,\ y)]$$
$$= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,\ y)\delta(r-x\cos\alpha-y\sin\alpha)\,dx\,dy, \quad (3)$$

where r is the PERPENDICULAR distance from a line to the origin and α is the ANGLE formed by the distance VECTOR.

Using the identity

$$\mathcal{F}[R[f(\omega,\alpha)]] = \mathcal{F}^2[f(u,\ v)], \quad (4)$$

where $\mathcal{F}$ is the FOURIER TRANSFORM, gives the inversion formula

$$f(x,y) = c\int_0^\pi\int_{-\infty}^{\infty}\mathcal{F}[R[f(\omega,\ \alpha)]]$$
$$\times |\omega| e^{i\omega(x\cos\alpha+y\sin\alpha)}\,d\omega\,d\alpha. \quad (5)$$

The FOURIER TRANSFORM can be eliminated by writing

$$f(x,y) = \int_0^\pi\int_{-\infty}^{\infty} R[f(r,\ \alpha)]W(r,\ \alpha,\ x,\ y)\,dr\,d\alpha, \quad (6)$$

where W is a WEIGHTING FUNCTION such as

$$W(r,\ \alpha,\ x,\ y) = h(x\cos\alpha+y\sin\alpha-r) = \mathcal{F}^{-1}[|\omega|]. \quad (7)$$

Nievergelt (1986) uses the inverse formula

$$f(x,\ y) = \frac{1}{\pi}\lim_{c\to 0}\int_0^\pi\int_{-\infty}^{\infty} R[f(r+x\cos\alpha$$
$$+y\sin\alpha,\ \alpha)]G_c(r)\,dr\,d\alpha, \quad (8)$$

where

$$G_c(r) = \begin{cases} \dfrac{1}{\pi c^2} & \text{for } |r|\le c \\ \dfrac{1}{\pi c^2}\left(1-\dfrac{1}{\sqrt{1-c^2/r^2}}\right) & \text{for } |r|>c. \end{cases} \quad (9)$$

LUDWIG'S INVERSION FORMULA expresses a function in terms of its Radon transform. $R'(r,\ \alpha)$ and $R(p,\ \tau)$ are related by

$$p = \cot \alpha \quad \tau = r \csc \alpha \tag{10}$$

$$r = \frac{\tau}{1 + p^2} \quad \alpha = \cot^{-1} p. \tag{11}$$

The Radon transform satisfies superposition

$$R(p,\ \tau)[f_1(x,\ y) + f_2(x,\ y)] = U_1(p,\ \tau) + U_2(p,\ \tau), \tag{12}$$

linearity

$$R(p,\ \tau)[af(x,\ y)] = aU(p,\ \tau), \tag{13}$$

scaling

$$R(p,\ \tau)\left[f\left(\frac{x}{a},\ \frac{y}{b}\right)\right] = |a| U\left(p\frac{a}{b},\ \frac{\tau}{b}\right), \tag{14}$$

ROTATION, with R_ϕ ROTATION by ANGLE ϕ

$$R(p,\ \tau)\left[R_\phi f(x,\ y)\right] = \frac{1}{|\cos \phi + p \sin \phi|} U \times \left(\frac{p - \tan \phi}{1 + p \tan \phi},\ \frac{\tau}{\cos \phi + p \sin \phi}\right), \tag{15}$$

and skewing

$$R(p,\ \tau)[f(ax + by,\ cx + dy)] = \frac{1}{|a + bp|} U\left[\frac{c + dp}{a + bp},\ \tau \frac{d - b(c + bd)}{a + bp}\right] \tag{16}$$

(Durrani and Bisset 1984).

The line integral along $p,\ \tau$ is

$$I = \sqrt{1 + p^2} U(p,\ \tau). \tag{17}$$

The analog of the 1-D CONVOLUTION THEOREM is

$$R(p,\ \tau)[f(x,\ y) * g(y)] = U(p,\ \tau) * g(\tau), \tag{18}$$

the analog of PLANCHEREL'S THEOREM is

$$\int_{-\infty}^{\infty} U(p,\ \tau)\, d\tau = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x,\ y)\, dx\, dy, \tag{19}$$

and the analog of PARSEVAL'S THEOREM is

$$\int_{-\infty}^{\infty} R(p,\ \tau)[f(x,\ y)]^2\, d\tau = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f^2(x,\ y)\, dx\, dy. \tag{20}$$

If f is a continuous function on $\mathbb{C}$, integrable with respect to a plane LEBESGUE MEASURE, and

$$\int_l f\, ds = 0 \tag{21}$$

for every (doubly) infinite line l where s is the length measure, then f must be identically zero. However, if the global integrability condition is removed, this result fails (Zalcman 1982, Goldstein 1993).

Radon Transform—Cylinder

Let the 2-D cylinder function be defined by

$$f(x,\ y) \equiv \begin{cases} 1 & \text{for } r < R \\ 0 & \text{for } r > R. \end{cases} \tag{1}$$

Then the Radon transform is given by

$$R(p,\ \tau)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,\ y)\delta[y-(\tau+px)]\ dy\ dx, \quad (2)$$

where

$$\delta(x)=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-ikx} \quad (3)$$

is the DELTA FUNCTION.

$$R(p,\ \tau)=\frac{1}{2\pi}\int_0^{2\pi}\int_0^R\int_{-\infty}^{\infty} e^{-ik(r\ \sin\ \theta-pr\ \cos\ \theta)}r\ dr\ d\theta\ dk$$

$$=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ikr}\int_0^{2\pi}\int_0^R e^{-ikr(\sin\ \theta-p\ \cos\ \theta)}r\ dr\ d\theta\ dk. \quad (4)$$

Now write

$$\sin\ \theta-p\ \cos\ \theta=\sqrt{1+p^2}\ \cos(\theta+\phi)\equiv\sqrt{1+p^2}\ \cos\ \theta', \quad (5)$$

with ϕ a phase shift. Then

$$R(p,\ \tau)=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ik\tau}$$

$$\times\int_0^R\left(\int_0^{2\pi} e^{-ik\sqrt{1+p^2}r\ \cos\ \theta'}\ d\theta'\right)r\ dr\ dk$$

$$=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ik\tau}\int_0^R 2\pi J_0\left(k\sqrt{1+p^2}r\right)r\ dr\ dk$$

$$=\int_{-\infty}^{\infty} e^{ik\tau}\int_0^R J_0\left(k\sqrt{1+p^2}r\right)r\ dr\ dk. \quad (6)$$

Then use

$$\int_0^z t^{n+1}J_n(t)\ dt=z^{n+1}J_{n+1}(z), \quad (7)$$

which, with $n=0$, becomes

$$\int_0^z tJ_0(t)\ dt=zJ_1(z). \quad (8)$$

Define

$$t\equiv k\sqrt{1+p^2}r \quad (9)$$

$$dt=k\sqrt{1+p^2}\ dr \quad (10)$$

$$r\ dr=\frac{t\ dt}{k^2(1+p^2)}, \quad (11)$$

so the inner integral is

$$\int_0^{R\sqrt{1+p^2}} J_0(t)\ \frac{t\ dt}{k^2(1+p^2)}$$

$$=\frac{1}{k^2(1+p^2)}\ kR\sqrt{1+p^2}J_1\left(kR\sqrt{1+p^2}\right) \quad (12)$$

$$=\frac{J_1\left(kR\sqrt{1+p^2}\right)}{k\sqrt{1+p^2}}\ R, \quad (13)$$

and the Radon transform becomes

$$R(p,\ \tau)=\frac{R}{\sqrt{1+p^2}}\int_{-\infty}^{\infty}\frac{e^{ik\tau}J_1\left(kR\sqrt{1+p^2}\right)}{k}\ dk$$

$$=\frac{2R}{\sqrt{1+p^2}}\int_0^{\infty}\frac{\cos(kr)J_1\left(kR\sqrt{1+p^2}\right)}{k}\ dk$$

$$=\begin{cases}\frac{2}{1+p^2}\ \sqrt{R^2(1+p^2)-\tau^2} & \text{for } \tau^2<R^2(1+p^2)\\ 0 & \text{for } \tau^2\geq R^2(1+p^2).\end{cases} \quad (14)$$

Converting to R' using $p=\cot\ \alpha$,

$$R'(r,\ \alpha)=\frac{2}{\sqrt{1+\cot^2\ \alpha}}\ \sqrt{(1+\cot^2\ \alpha)R^2-r^2\ \csc^2\ \alpha}$$

$$=\frac{2}{\csc\ \alpha}\ \sqrt{\csc^2\ \alpha R^2-r^2\ \csc^2\ \alpha}$$

$$=2\sqrt{R^2-r^2}, \quad (15)$$

which could have been derived more simply by

$$R'(r,\ \alpha)=\int_{-\sqrt{R^2-r^2}}^{\sqrt{R^2-r^2}} dy. \quad (16)$$

Radon Transform—Delta Function

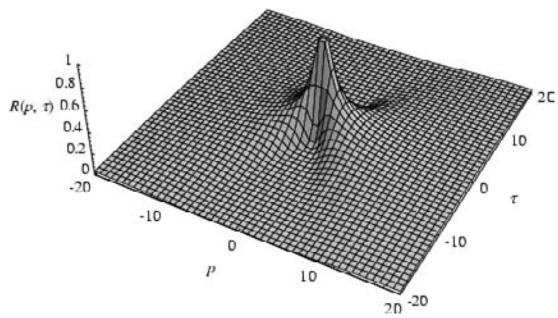
For a DELTA FUNCTION at $(x_0,\ y_0)$,

$$R(p,\ \tau)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\delta(x-x_0)\delta(y-y_0)$$

$$\times\delta[y-(\tau+px)]\ dy\ dx$$

$$=\frac{1}{2\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-ik[y-(\tau+px)]}\delta(x-x_0)$$

$$\times\delta(y-y_0)\ dk\ dy\ dx$$



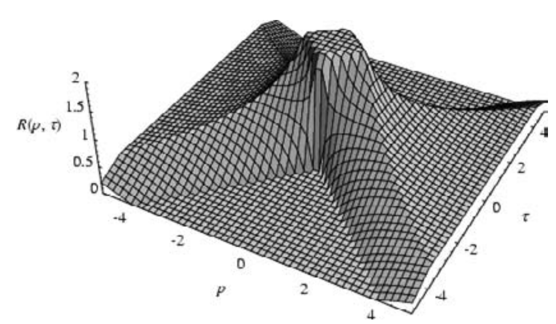
$$=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ik\tau}\left[\int_{-\infty}^{\infty} e^{-iky}\delta(y-y_0)\ dy\right.$$

$$\left.\times\int_{-\infty}^{\infty} e^{ikpx}\delta(x-x_0)\ dx\right]\ dk$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ik\tau} e^{-iky_0} e^{ikpx_0}\, dk.$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ik(\tau + px_0 - y_0)}\, dk = \delta(\tau + px_0 - y_0).$$

Radon Transform—Gaussian



$$R(p,\ \tau) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left[\frac{1}{\sigma\sqrt{2\pi}}\, e^{-(x^2+y^2)/2\sigma^2} \right] \times \delta[y - (\tau + px)]\, dy\, dx$$

$$= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\left[x^2 + (\tau + px)^2\right]/2\sigma^2|}\, dx$$

$$= \frac{1}{\sqrt{1+p^2}}\, e^{-t^2/\left[2\left(1+p^2\right)\sigma^2\right]}.$$

Radon Transform—Square

$$R(p,\ \tau) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x,\ y) \delta[y - (\tau + px)]\, dy\, dx, \quad (1)$$

where

$$f(x,\ y) \equiv \begin{cases} 1 & \text{for } x,\ y \in [-a,\ a] \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

and

$$\delta(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-ikx} \quad (3)$$

is the DELTA FUNCTION.

$$R(p,\ r) = \frac{1}{2\pi} \int_{-a}^{a} \int_{-a}^{a} \int_{-\infty}^{\infty} e^{-ik[y-(r+px)]}\, dk\, dy\, dx$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ikr} \left[\int_{-a}^{a} e^{-ky}\, dy \int_{-a}^{a} e^{ikpx}\, dx \right] dk$$

$$= \frac{1}{2\pi}\, e^{ikr} \frac{1}{-ik} \left[e^{-iky}\right]_{-a}^{a} \frac{1}{ikp} \left[e^{-ikpx}\right]_{-a}^{a} dk$$

$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ikr} \frac{1}{k^2 p} [-2i \sin(ka)][2i \sin(kpa)]\, dk$$

$$= \frac{2}{\pi p} \int_{-\infty}^{\infty} \frac{\sin(ka) \sin(kpa) e^{ikr}}{k^2}\, dk$$

$$= \frac{4}{\pi p} \int_{-\infty}^{\infty} \frac{\sin(ka) \sin(kpa) \cos(k\tau)}{k^2}\, dk$$

$$= \frac{2}{\pi p} \int_{-\infty}^{\infty} \frac{\sin[k(\tau + a)] - \sin[k(\tau - a)]}{k^2} \sin(kpa)\, dk$$

$$= \frac{2}{\pi p} \left\{ \int_0^{\infty} \frac{\sin[k(\tau + a)] \sin(kpa)}{k^2}\, dk - \int_0^{\infty} \frac{\sin[k(\tau - a)] \sin(kpa)}{k^2}\, dk \right\}. \quad (4)$$

From Gradshteyn and Ryzhik (2000, equation 3.741.3),

$$\int_0^{\infty} \frac{\sin(ax) \sin(bx)}{x^2}\, dx = \tfrac{1}{2} \pi \operatorname{sgn}(ab) \min(|a|,\ |b|), \quad (5)$$

so

$$R(p,\ \tau) = \frac{1}{p} \{ \operatorname{sgn}[(\tau + a)pa] \min(|\tau + a|,\ |pa|) - \operatorname{sgn}[(\tau - a)pa] \min(|\tau - a|,\ |pa|) \}. \quad (6)$$

Radon-Nikodym Derivative

When a MEASURE λ is ABSOLUTELY CONTINUOUS with respect to a positive measure μ, then it can be written as

$$\lambda(E) = \int_E f\, d\mu.$$

By analogy with the first FUNDAMENTAL THEOREM OF CALCULUS, the function f is called the Radon-Nikodym derivative of λ with respect to μ. Sometimes it is denoted $d\lambda/d\mu$ or $D\lambda/D\mu$.

See also Absolutely Continuous, Complex Measure, Fundamental Theorems of Calculus, Lebesgue Measure, Polar Representation (Measure), Radon-Nikodym Theorem

References

Rudin, W. *Real and Complex Analysis.* New York: McGraw-Hill, p. 122, 1987.

Radon-Nikodym Theorem

The Radon-Nikodym theorem asserts that any absolutely continuous measure λ with respect to some positive measure μ (which could be Lebesgue measure or Haar measure) is given by the integral of some L^1-function f,

$$\lambda(E) = \int_E f\, d\mu. \quad (1)$$

The function f is like a density function for the measure.

A closely related theorem says that any complex measure λ decomposes into an absolutely continuous measure λ_a and a singular measure λ_c. This is the Lebesgue decomposition

$$\lambda = \lambda_a + \lambda_c. \quad (2)$$

One consequence of the Radon-Nikodym theorem is that any complex measure has a polar representation,

$$d\mu = hd|\mu|, \quad (3)$$

with $|h| = 1$.

See also Absolutely Continuous, Complex Measure, Haar Measure, Lebesgue Decomposition (Measure), Lebesgue Measure, Polar Representation (Measure), Singular Measure

Rado's Sigma Function

Busy Beaver

Railroad Track Problem

Given a straight segment of track of length l, add a small segment Δl so that the track bows into a circular arc. Find the maximum displacement d of the bowed track. The Pythagorean theorem gives

$$R^2 = x^2 + (\tfrac{1}{2}l)^2. \quad (1)$$

But R is simply $x+d$, so

$$R^2 = (x+d)^2 = x^2 = x^2 + 2xd + d^2. \quad (2)$$

Solving (1) and (2) for x gives

$$x = \frac{\frac{1}{4}l^2 - d^2}{2d}. \quad (3)$$

Expressing the length of the arc in terms of the central angle,

$$\begin{aligned}\tfrac{1}{2}(l+\Delta l) = \theta(d+x) &= \theta\left(d + \frac{\frac{1}{4}l^2 - d^2}{2d}\right)\\ &= \theta\left(\frac{2d^2 + \frac{1}{4}l^2 - d^2}{2d}\right)\\ &= \theta\left(\frac{d^2 + \frac{1}{4}l^2}{2d}\right). \quad (4)\end{aligned}$$

But θ is given by

$$\tan\theta = \frac{\frac{1}{2}l}{x} = \frac{\frac{1}{2}l(2d)}{\frac{1}{4}l^2 - d^2} = \frac{dl}{\frac{1}{4}l^2 - d^2}, \quad (5)$$

so plugging θ in gives

$$\tfrac{1}{2}(l+\Delta l) = \left(\frac{d^2+\frac{1}{4}l^2}{2d}\right)\tan^{-1}\left(\frac{dl}{\frac{1}{4}l^2-d^2}\right) \quad (6)$$

$$d(l+\Delta l) = \left(d^2+\tfrac{1}{4}l^2\right)\tan^{-1}\left(\frac{dl}{\frac{1}{4}l^2-d^2}\right). \quad (7)$$

For $l \gg d$,

$$\frac{dl}{\frac{1}{4}l^2\left(1-\frac{d^2}{4l^2}\right)} = \frac{4d}{l}\left(1-\frac{4d^2}{l^2}\right)^{-1} \approx \frac{4d}{l}\left(1+\frac{4d}{l^2}\right). \quad (8)$$

Therefore,

$$d(l+\Delta l) \approx (d^2+\tfrac{1}{4}l^2) \times\left\{\frac{4d}{l}\left(1+\frac{4d^2}{l^2}\right)-\frac{1}{3}\left[\frac{4d}{l}\left(1+\frac{4d^2}{l^2}\right)\right]^3\right\}$$

$$\approx \left(d^2+\tfrac{1}{4}l^2\right)\left[\frac{4d}{l}+\frac{16d^3}{l^3}-\frac{1}{3}\left(\frac{4d}{l}\right)^3 \times\left(1+3\,\frac{4d^2}{l^2}\right)\right]. \quad (9)$$

Keeping only terms to order $(d/l)^3$,

$$dl+\Delta l \approx \frac{4d^3}{l}+dl+\frac{4d^3}{l}-\frac{16}{3}\,\frac{d^3}{l} \quad (10)$$

$$\Delta l \approx \left(8-\tfrac{16}{3}\right)\frac{d^3}{l} = \frac{24-16}{3}\,\frac{d^3}{l} = \frac{8}{3}\,\frac{d^3}{l}, \quad (11)$$

so

$$d^2 = \tfrac{3}{8}\,l\Delta l \quad (12)$$

and

$$d \approx \tfrac{1}{2}\sqrt{\tfrac{3}{2}\,l\Delta l} = \tfrac{1}{4}\sqrt{6l\Delta l}. \quad (13)$$

If we take $l = 1$ mile $= 5280$ feet and $\Delta l = 1$ foot, then $d \approx 44.50$ feet.

Ramanujan 6–10–8 Identity

Let $ad = bc$, then

$$64[(a+b+c)^6+(b+c+d)^6-(c+d+a)^6 -(d+a+b)^6+(a-b)^6-(b-c)^6]$$
$$\times[(a+b+c)^{10}+(b+c+d)^{10}-(c+d+a)^{10} -(d+a+b)^{10}+(a-d)^{10}-(b-c)^{10}]$$
$$=45[(a+b+c)^8+(b+c+d)^8-(c+d+a)^8 -(d+a+b)^8+(a-d)^8-(b-c)^8]^2. \quad (1)$$

This can also be expressed by defining

$$F_{2m}(a,\ b,\ c,\ d) = (a+b+c)^{2m}+(b+c+d)^{2m} -(c+d+a)^{2m}-(d+a+b)^{2m}+(a-d)^{2m}-(b-c)^{2m} \quad (2)$$

$$f_{2m}(x,\ y) = (1+x+y)^{2m}+(x+y+xy)^{2m}-(y+xy+1)^{2m} -(xy+1+x)^{2m}+(1-xy)^{2m}-(x-y)^{2m}. \quad (3)$$

Then

$$F_{2m}(a,\ b,\ c,\ d) = a^{2m}f_{2m}(x,\ y), \quad (4)$$

and identity (1) can then be written

$$64f_6(x,\ y)f_{10}(x,\ y) = 45f_8^2(x,\ y). \quad (5)$$

Incidentally,

$$f_2(x,\ y) = 0 \quad (6)$$

$$f_4(x,\ y) = 0. \quad (7)$$

Ramanujan Constant

The IRRATIONAL constant

$$R \equiv e^{\pi\sqrt{163}} = 262537412640768743.99999999999925\ldots$$

which is very close to an INTEGER. Numbers such as the Ramanujan constant can be found using the theory of MODULAR FUNCTIONS. In fact, the nine HEEGNER NUMBERS (which include 163) share a deep number theoretic property related to some amazing properties of the J-FUNCTION that leads to this sort of near-identity.

Although Ramanujan (1913–14) gave few rather spectacular examples of almost integers (such $e^{\pi\sqrt{58}}$), he did not actually mention particular near-identity

give above. In fact, the first to observe this property of 163 was Hermite (1859). The name "Ramanujan's constant" seems to derive from an April Fool's joke played by Martin Gardner (Apr. 1975) on the readers of *Scientific American*. In his column, Gardner claimed that $e^{\pi\sqrt{163}}$ was exactly an INTEGER, and that Ramanujan had conjectured this in his 1914 paper. Gardner admitted his hoax a few months later (Gardner, July 1975).

Ramanujan Continued Fraction

ROGERS-RAMANUJAN CONTINUED FRACTION

Ramanujan Cos/Cosh Identity

The amazing identity

$$\left[1+2\sum_{n=1}^{\infty}\frac{\cos(n\theta)}{\cosh(n\pi)}\right]^{-2}+\left[1+2\sum_{n=1}^{\infty}\frac{\cosh(n\theta)}{\cosh(n\pi)}\right]^{-2}=\frac{2\Gamma^4\left(\frac{3}{4}\right)}{\pi}$$

for all θ, where $\Gamma(z)$ is the GAMMA FUNCTION. Equating coefficients of θ^0, θ^4, and θ^8 gives some amazing identities for the HYPERBOLIC SECANT.

See also HYPERBOLIC SECANT

Ramanujan Function

The two-argument Ramanujan function is defined by

$$\phi(a,\ n)\equiv 1+2\sum_{k=1}^{n}\frac{1}{(ak)^3-ak} \tag{1}$$

$$=1-\frac{1}{a}\left(H_{-1/a}+H_{1/a}+2H_n-H_{n-1/a}-H_{n+1/a}\right). \tag{2}$$

The one-argument function $\phi(a)$ is then defined as the limiting sum of $\phi(a,\ n)$ as $n\to\infty$,

$$\phi(a)\equiv\lim_{n\to\infty}\phi(a,\ n)=1+2\sum_{k=1}^{\infty}\frac{1}{(ak)^3-ak} \tag{3}$$

$$=-\frac{1}{a}\left[\psi_0\left(\frac{1}{a}\right)+\psi_0\left(1-\frac{1}{a}\right)+2\gamma\right], \tag{4}$$

$$=1-\frac{1}{a}\left(H_{-1/a}+H_{1/a}\right) \tag{5}$$

where $\psi_0(x)$ is the DIGAMMA FUNCTION, γ is the EULER-MASCHERONI CONSTANT, and H_ν is a HARMONIC NUMBER. The values of $\phi(n)$ for $n=2$, 3, ... are

$$\phi(2)=2\ln 2$$

$$\phi(3)=\ln 3$$

$$\phi(4)=\tfrac{3}{2}\ln 2$$

$$\phi(5)=\tfrac{1}{5}\sqrt{5}\ln\phi+\tfrac{1}{2}\ln 5$$

$$\phi(6)=\tfrac{1}{2}\ln 3+\tfrac{2}{3}\ln 2,$$

where ϕ is the GOLDEN RATIO.

See also HARMONIC NUMBER, RAMANUJAN g- AND G-FUNCTIONS, TAU FUNCTION

Ramanujan g- and G-Functions

Following Ramanujan (1913–14), write

$$\prod_{k=1,\ 3,\ 5,\ \ldots}^{\infty}\left(1+e^{-k\pi\sqrt{n}}\right)=2^{1/4}e^{-\pi\sqrt{n}/24}G_n \tag{1}$$

$$\prod_{k=1,\ 3,\ 5,\ \ldots}^{\infty}\left(1+e^{-k\pi\sqrt{n}}\right)=2^{1/4}e^{-\pi\sqrt{n}/24}g_n. \tag{2}$$

These satisfy the equalities

$$g_{4n}=2^{1/4}g_nG_n \tag{3}$$

$$G_n=G_{1/n} \tag{4}$$

$$g_n^{-1}=g_{4/n} \tag{5}$$

$$\tfrac{1}{4}=(g_nG_n)^8(G_n^8-g_n^8). \tag{6}$$

G_n and g_n can be derived using the theory of MODULAR FUNCTIONS and can always be expressed as roots of algebraic equations when n is RATIONAL. For simplicity, Ramanujan tabulated g_n for n EVEN and G_n for n ODD. However, (6) allows G_n and g_n to be solved for in terms of g_n and G_n, giving

$$g_n = \tfrac{1}{2}\left(G_n^8 + \sqrt{G_n^{16} - G_n^{-8}}\right)^{1/8} \quad (7)$$

$$G_n = \tfrac{1}{2}\left(g_n^8 + \sqrt{g_n^{16} + Gg_n^{-8}}\right)^{1/8}. \quad (8)$$

Using (3) and the above two equations allows g_{4n} to be computed in terms of g_n or G_n

$$g_{4n} = \begin{cases} 2^{1/8} g_n \left(g_n^8 + \sqrt{g_n^{16} + g_n^{-8}}\right)^{1/8} & \text{for } n \text{ even} \\ 2^{1/8} G_n \left(G_n^8 + \sqrt{G_n^{16} + G_n^{-8}}\right)^{1/8} & \text{for } n \text{ odd.} \end{cases} \quad (9)$$

In terms of the PARAMETER k and complementary PARAMETER k',

$$G_n = (2k_n k_n')^{-1/12} \quad (10)$$

$$g_n = \left(\frac{k_n'^{\,2}}{2k}\right)^{1/12}. \quad (11)$$

Here,

$$k_n = \lambda^*(n) \quad (12)$$

is the ELLIPTIC LAMBDA FUNCTION, which gives the value of k for which

$$\frac{K'(k)}{K(k)} = \sqrt{n}. \quad (13)$$

Solving for $\lambda^*(n)$ gives

$$\lambda^*(n) = \tfrac{1}{2}\left[\sqrt{1 + G_n^{-12}} - \sqrt{1 - G_n^{-12}}\right] \quad (14)$$

$$\lambda^*(n) = g_n^6\left[\sqrt{g_n^{12} + g_n^{-12}} - g_n^6\right]. \quad (15)$$

Analytic values for small values of n can be found in Ramanujan (1913–1914) and Borwein and Borwein (1987), and have been compiled by Weisstein. Ramanujan (1913–1914) contains a typographical error labeling G_{465} as G_{265}.

Ramanujan Psi Sum

A sum which includes both the JACOBI TRIPLE PRODUCT and the Q-BINOMIAL THEOREM as special cases. Ramanujan's sum is

$$\sum_{n=-\infty}^{\infty} \frac{(a)_n}{(b)_n} x^n = \frac{(ax)_\infty (q/ax)_\infty (q)_\infty (b/a)_\infty}{(x)_\infty (b/ax)_\infty (b)_\infty (q/a)_\infty},$$

where the NOTATION $(q)_k$ denotes Q-SERIES. For $b = q$, this becomes the Q-BINOMIAL THEOREM.

See also JACOBI TRIPLE PRODUCT, Q-BINOMIAL THEOREM, Q-SERIES

Ramanujan Theta Functions

Ramanujan's one-variable theta function is defined by

$$\varphi(q) \equiv \sum_{m=-\infty}^{\infty} q^{m^2}, \quad (1)$$

$$= \vartheta_3(0, q) \quad (2)$$

where $\vartheta_3(0, q)$ is a JACOBI THETA FUNCTION, and is equal to the JACOBI TRIPLE PRODUCT with $z = 1$. Special values include

$$\varphi\left(e^{-\pi\sqrt{2}}\right) = \frac{\Gamma\left(\frac{9}{8}\right)}{\Gamma\left(\frac{5}{4}\right)}\sqrt{\frac{\Gamma\left(\frac{1}{4}\right)}{2^{1/4}\pi}} \quad (3)$$

$$\varphi(e^{-\pi}) = \frac{\pi^{1/4}}{\Gamma\left(\frac{3}{4}\right)}, \quad (4)$$

where $\Gamma(x)$ is a GAMMA FUNCTION.

Another function sometimes given the same symbol is

$$\varphi(q) = \sqrt{\frac{\vartheta_2(0, q)}{\vartheta_3(0, q)}}, \quad (5)$$

where $\vartheta_i(0, q)$ is again a JACOBI THETA FUNCTION, which has special value

$$\varphi\left(-e^{-\pi\sqrt{3}}\right) = \left(4\sqrt{3} - 7\right)^{1/8}. \quad (6)$$

Ramanujan's two-variable theta function is defined by

$$f(a, b) \equiv \sum_{n=-\infty}^{\infty} a^{n(n+1)/2} b^{n(n-1)/2} \quad (7)$$

for $|ab| < 1$ (Berndt *et al.*). It is a generalization of the function $\varphi(x)$

$$f(x, x) = \varphi(x) \quad (8)$$

and satisfies

$$f(-1, a) = 0 \quad (9)$$

$$f(a, b) = f(b, a) = (-a;\ ab)_\infty (-b;\ ab)_\infty (ab;\ ab)_\infty \quad (10)$$

$$f(-q) \equiv f(-q, -q^2) \quad (11)$$

$$= \sum_{k=0}^{\infty} (-1)^k q^{k(2k-1)/2} \sum_{k=1}^{\infty} (-1)^k q^{k(2k+1)/2} \quad (12)$$

$$= (q;\ q)_\infty \quad (13)$$

(Berndt *et al.*), where $(a;\ q)_\infty$ is a Q-POCHHAMMER

SYMBOL. (13) is equivalent to EULER'S PENTAGONAL NUMBER THEOREM.

See also EULER'S PENTAGONAL NUMBER THEOREM, JACOBI TRIPLE PRODUCT, *Q*-SERIES, ROGERS-RAMANUJAN CONTINUED FRACTION, SCHRÖTER'S FORMULA

Ramanujan's Square Equation

The DIOPHANTINE EQUATION

$$2^n-7=x^2.$$

It has been proved that the only solutions to this equation are $n=3$, 4, 5, 7, and 15 (Beeler *et al.* 1972, Item 31).

References

Schroeppel, R. C. Item 31 in Beeler, M.; Gosper, R. W.; and Schroeppel, R. *HAKMEM.* Cambridge, MA: MIT Artificial Intelligence Laboratory, Memo AIM-239, p. 14, Feb. 1972.

Ramanujan's Sum

The sum

$$c_q(m)=\sum_{h^*(q)}e^{2\pi ihm/q}, \quad (1)$$

where h runs through the residues RELATIVELY PRIME to q, which is important in the representation of numbers by the sums of squares. If $(q,\ q')=1$ (i.e., q and q' are RELATIVELY PRIME), then

$$c_{qq'}(m)=c_q(m)c_{q'}(m). \quad (2)$$

For argument 1,

$$c_b(1)=\mu(b), \quad (3)$$

where μ is the MÖBIUS FUNCTION, and for general m,

$$c_b(m)=\mu\left(\frac{b}{(b,\ m)}\right)\frac{\phi(b)}{\phi\left(\frac{b}{(b,\ m)}\right)}. \quad (4)$$

See also MÖBIUS FUNCTION, WEYL'S CRITERION

Ramanujan's Sum Identity

If

$$\frac{1+53x+9x^2}{1-82x-82x^2+x^3}=\sum_{n=1}^{\infty}a_nx^n \quad (1)$$

$$\frac{2-26x-12x^2}{1-82x-82x^2+x^3}=\sum_{n=0}^{\infty}b_nx^n \quad (2)$$

$$\frac{2+8x-10x^2}{1-82x-82x^2+x^3}=\sum_{n=0}^{\infty}c_nx^n \quad (3)$$

(Sloane's A051028, A051029, and A051030), then

$$a_n^3+b_n^3=c_n^3+(-1)^n. \quad (4)$$

Hirschhorn (1995) showed that

$$a_n=\tfrac{1}{85}\left[\left(64+8\sqrt{85}\right)\alpha^n+\left(64-8\sqrt{85}\right)\beta^n-43(-1)^n\right] \quad (5)$$

$$b_n=\tfrac{1}{85}\left[\left(77+7\sqrt{85}\right)\alpha^n+\left(77-7\sqrt{85}\right)\beta^n-16(-1)^n\right] \quad (6)$$

$$c_n=\tfrac{1}{85}\left[\left(93+9\sqrt{85}\right)\alpha^n+\left(93-9\sqrt{85}\right)\beta^n-16(-1)^n\right], \quad (7)$$

where

$$\alpha=\tfrac{1}{2}\left(83+9\sqrt{85}\right) \quad (8)$$

$$\beta=\tfrac{1}{2}\left(83-9\sqrt{85}\right). \quad (9)$$

Hirschhorn (1996) showed that checking the first seven cases $n=0$ to 6 is sufficient to prove the result.

Ramsey Number

The Ramsey number $R(m, n)$ gives the solution to the PARTY PROBLEM, which asks the minimum number of guests $R(m, n)$ that must be invited so that at least m will know each other or at least n will not know each other. In the language of GRAPH THEORY, the Ramsey number is the minimum number of vertices $v = R(m, n)$ such that all undirected simple graphs of order v contain a CLIQUE of order m *or* an INDEPENDENT SET of order n. RAMSEY'S THEOREM states that such a number exists for all m and n.

By symmetry, it is true that

$$R(m, n) = R(n, m). \quad (1)$$

It also must be true that

$$R(m, 2) = m. \quad (2)$$

A generalized Ramsey number is written

$$R(m_1, \ldots, m_k;\ n) \quad (3)$$

and is the smallest INTEGER r such that, no matter how each n-element SUBSET of an r-element SET is colored with k colors, there exists an i such that there is a SUBSET of size m_i, all of whose n-element SUBSETS are color i. The usual Ramsey numbers are then equivalent to $R(m, n) = R(m, n;\ 2)$.

Bounds are given by

$$R(k, l) \le \begin{cases} R(k-1, l) + R(k, l-1) - 1 & \text{for } R(k-1, 1) \text{ and } R(k, l-1) \text{ even} \\ R(k-1, l) + R(k, l-1) & \text{otherwise} \end{cases} \quad (4)$$

and

$$R(k, k) \le 4R(k-2, k) + 2 \quad (5)$$

(Chung and Grinstead 1983). Erdos proved that for diagonal Ramsey numbers $R(k, k)$,

$$\frac{k 2^{k/2}}{e\sqrt{2}} < R(k, k). \quad (6)$$

This result was subsequently improved by a factor of 2 by Spencer (1975). $R(3, k)$ was known since 1980 to be bounded from above by $c_2 k^2 / \ln k$, and Griggs (1983) showed that $c_2 = 5/12$ was an acceptable limit. J.-H. Kim (Cipra 1995) subsequently bounded $R(3, k)$ by a similar expression from below, so

$$c_1 \frac{k^2}{\ln k} \leq R(3, k) \leq c_2 \frac{k^2}{\ln k}. \qquad (7)$$

Burr (1983) gives Ramsey numbers for all 113 graphs with no more than 6 EDGES and no isolated points.

A summary of known results up to 1983 for $R(m, n)$ is given in Chung and Grinstead (1983). Radziszowski (1999) maintains an up-to-date list of the best current bounds, reproduced in part in the following table for $R(m, n; 2)$.

Ramsey Theory

The mathematical study of combinatorial objects in which a certain degree of order must occur as the scale of the object becomes large. Ramsey theory is named after Frank Plumpton Ramsey, who did seminal work in this area before his untimely death at age 26 in 1930. The theory was subsequently developed extensively by Erdos.

The classical problem in Ramsey theory is the PARTY PROBLEM, which asks the minimum number of guests $R(m, n)$ that must be invited so that at least m will know each other (i.e., there exists a CLIQUE of order m) or at least n will not know each other (i.e., there exists an INDEPENDENT SET of order n. Here, $R(m, n)$ is called a RAMSEY NUMBER.

A typical result in Ramsey theory states that if some mathematical object is partitioned into finitely many parts, then one of the parts must contain a subobject of an interesting kind. For example, it is known that if n is large enough and V is an n-dimensional VECTOR SPACE over the FIELD of integers (mod p), then however V is partitioned into r pieces, one of the pieces contains an affine subspace of dimension d.

Ramsey's Theorem

A generalization of DILWORTH'S LEMMA. For each $m, n \in \mathbb{N}$ with $m, n \geq 2$, there exists a least INTEGER $R(m, n)$ (the RAMSEY NUMBER) such that no matter how the COMPLETE GRAPH $K_{R(m, n)}$ is two-colored, it will contain a green SUBGRAPH K_m or a red SUBGRAPH K_n. Furthermore,

$$R(m,n) \leq R(m-1,n) + R(m,n-1)$$

if $m, n \geq 3$.

The theorem can be equivalently stated that, for all $m \in \mathbb{N}$, there exists an $n \in \mathbb{N}$ such that any COMPLETE DIGRAPH on n VERTICES contains a COMPLETE TRANSITIVE SUBGRAPH of m VERTICES.

Ramsey's theorem is a generalization of the PIGEONHOLE PRINCIPLE since

$$R(\underbrace{2,\ 2,\ \ldots,\ 2}_{t}) = t+1.$$

Random Composition

A random composition of a number n in k parts is one of the $\binom{n+k-1}{n}$ possible COMPOSITIONS of n, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. A random composition can be given by `RandomComposition[n, k]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Random Dot Stereogram

STEREOGRAM

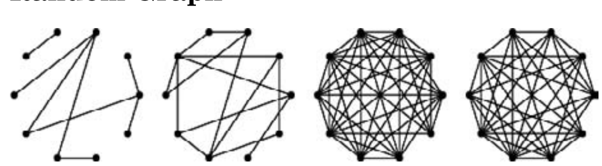
Random Fibonacci Sequence

Consider the Fibonacci-like recurrence

$$a_n = \pm a_{n-1} \pm a_{n-2},$$

where $a_0 = 0$, $a_1 = 1$, and each sign is chosen independently and at random with probability 1/2. Surprisingly, Viswanath (2000) showed that

$$\lim_{n\to\infty} |a_n|^{1/n} = 1.13198824\ldots$$



with probability one. This constant can be numerically computed by computing the product of a certain set of RANDOM MATRICES, and taking the SPECTRAL NORM of the result (Viswanath 2000).

Random Graph

A random graph is a GRAPH in which properties such as the number of NODES, EDGES, and connections

between them are determined in some random way. The graphs illustrated above are random graphs on 10 edges with edge probabilities distributed uniformly in [0, 1].

Erdos and Rényi (1960) showed that for many monotone-increasing properties of random graphs, graphs of a size slightly less than a certain threshold are very unlikely to have the property, whereas graphs with a few more EDGES are almost certain to have it. This is known as a PHASE TRANSITION (Janson *et al.* 2000, p. 103). Almost all graphs are connected and nonplanar (Skiena 1990, p. 156).

See also GRAPH, GRAPH THEORY, PHASE TRANSITION

Random Matrix

A random matrix is a MATRIX of given type and size whose entries consist of random numbers from some specified distribution.

If n matrices M_i are chosen with probability 1/2 from one of

$$M_+ = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix} \tag{1}$$

$$M_- = \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}, \tag{2}$$

then

$$\lim_{n\to\infty} \frac{\ln\|M_1 \cdots M_n\|}{n} = c, \tag{3}$$

where $e^c = 1.13198824\ldots$ and $\|M\|$ denotes the matrix SPECTRAL NORM (Bougerol and Lacroix 1985, pp. 11 and 157; Viswanath 2000). This is the same constant appearing in the RANDOM FIBONACCI SEQUENCE. The following *Mathematica* code can be used to estimate this constant.

```
n = 100000;
  m = Fold[Dot, IdentityMatrix[2],
       {{0,  1},  {1,  #}}  &  /@  ((-
1)^Table[Random[Integer], {n}])
  ]//N;
  Log[Sqrt[Max[Eigenvalues[Transpose[m].m]]]]/
n
```

Random Normal Deviates

NORMAL DEVIATES

Random Number

Computer-generated random numbers are sometimes called PSEUDORANDOM NUMBERS, while the term "random" is reserved for the output of unpredictable physical processes. When used without qualification, the word "random" usually means "random with a UNIFORM DISTRIBUTION." Other distributions are, of course possible. For example, the BOX-MULLER TRANSFORMATION allows random numbers with a 2-D uniform distribution to be transformed to corresponding random numbers with a 2-D Gaussian distribution. Similarly, in order to generate a power-law distribution $P(x)$ from a uniform distribution $P(y)$, write $P(x) = Cx^n$ for $x \in [x_0, x_1]$. Then normalization gives

$$\int_{x_0}^{x_1} P(x)\,dx = c\,\frac{[x^{n+1}]_{x_0}^{x_1}}{n+1} = 1, \tag{1}$$

so

$$C = \frac{n+1}{x_1^{n+1} - x_0^{n+1}}. \tag{2}$$

Let y be a uniformly distributed variate on [0, 1]. Then

$$D(x) = \int_{x_0}^{x} P(x')\,dx' = C\int_{x_0}^{x} x'^n\,dx'$$

$$= \frac{C}{n+1}\left(x^{n+1} - x_0^{n+1}\right) \equiv y, \tag{3}$$

and the variate given by

$$x = \left(\frac{n+1}{C}\,y + x_0^{n+1}\right)^{1/(n+1)}$$

$$= \left[\left(x_1^{n+1} - x_0^{n+1}\right)y + x_0^{n+1}\right]^{1/(n+1)} \tag{4}$$

is distributed as $P(x)$.

It is impossible to produce an arbitrarily long string of random digits and prove it is random. Strangely, it is very difficult for humans to produce a string of random digits, and computer programs can be written which, on average, actually predict some of the digits humans will write down based on previous ones.

The LINEAR CONGRUENCE METHOD is one algorithm for generating PSEUDORANDOM NUMBERS. The initial number used as the starting point in a random number generating algorithm is known as the SEED. The goodness of random numbers generated by a given ALGORITHM can be analyzed by examining its NOISE SPHERE.

When generating random numbers over some specified boundary, it is often necessary to normalize the distributions so that each differential area can is equally populated. For example, picking θ and ϕ from uniform distributions *does not* give a uniform distribution for SPHERE POINT PICKING.

Random Partition

A random partition of a number n is one of the $P(n)$ possible PARTITIONS of n, where $P(n)$ is the PARTITION FUNCTION P. A random partition can be given by `RandomPartition[n]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Random Percolation

PERCOLATION THEORY

Random Permutation

A PERMUTATION containing a fixed number n of a random selection from a given set of elements. There are two main algorithms for constructing random permutations. The first constructs a vector of random real numbers and uses them as keys to records containing the integers 1 to n. The second starts with an arbitrary permutation and then exchanges the ith element with a randomly selected one from the first i elements for $i = 1, ..., n$ (Skiena 1990).

There are an average of $n(n-1)/4$ PERMUTATION INVERSIONS in a PERMUTATION on n elements (Skiena 1990, p. 29).

Random Polygon

A random polygon is a POLYGON generated in some random way. Kendall conjectured that the shape of a random polygon is close to a DISK as the area of the polygon becomes large (Stoyan *et al.* 1987, Kovalenko 1999)

Random Tableau

A YOUNG TABLEAU chosen at random from those having a given shape. A random tableau can be generated by `RandomTableau[`*shape*`]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`). The figure above shows four random tableaux of the 21 distinct ones of shape {3, 2, 2}.

Random Variable

A random variable is a measurable function from a PROBABILITY SPACE $(S, \mathbb{S}, P)$ into a MEASURABLE SPACE $(S', \mathbb{S}')$ known as the STATE SPACE (Doob 1996). Papoulis (1984, p. 88) gives the slightly different definition of a random variable X as a REAL FUNCTION whose domain is the PROBABILITY SPACE S and such that:

1. The set $\{X \leq x\}$ is an EVENT for any real number x.
2. The probability of the events $\{X = +\infty\}$ and $\{X = -\infty\}$ equals zero.

The abbreviation "r.v." is sometimes used to denote a random variable.

Random Walk

A random process consisting of a sequence of discrete steps of fixed length. The random thermal perturbations in a liquid are responsible for a random walk phenomenon known as Brownian motion, and the collisions of molecules in a gas are a random walk responsible for diffusion. Random walks have interesting mathematical properties that vary greatly depending on the dimension in which the walk occurs and whether it is confined to a lattice.

Random Walk—1-D

Let N steps of equal length be taken along a LINE. Let p be the probability of taking a step to the right, q the probability of taking a step to the left, n_1 the number of steps taken to the right, and n_2 the number of steps taken to the left. The quantities p, q, n_1, n_2, and N are related by

$$p + q = 1 \tag{1}$$

and

$$n_1 + n_2 = N. \tag{2}$$

Now examine the probability of taking exactly n_1 steps out of N to the right. There are $\binom{N}{n_1} = \binom{n_1+n_2}{n_1}$ ways of taking n_1 steps to the right and n_2 to the left, where $\binom{n}{m}$ is a BINOMIAL COEFFICIENT. The probability of taking a particular ordered sequence of n_1 and n_2 steps is $p^{n_1}q^{n_2}$. Therefore,

$$P(n_1) = \frac{(n_1 + n_2)!}{n_1!n_2!}\, p^{n_1}q^{n_2} = \frac{N!}{n_1!(N-n_1)!}\, p^{n_1}q^{N-n_1}, \tag{3}$$

where $n!$ is a FACTORIAL. This is a BINOMIAL DISTRIBUTION and satisfies

$$\sum_{n_1=0}^{N} P(n_1) = (p+q)^N = 1^N = 1. \tag{4}$$

The MEAN number of steps n_1 to the right is then

$$\langle n_1 \rangle \equiv \sum_{n_1=0}^{N} n_1 P(n_1) = \sum_{n_1=0}^{N} \frac{N!}{n_1!(N-n_1)!}\, p^{n_1}q^{N-n_1}n_1, \tag{5}$$

but

$$n_1 p^{n_1} = p\,\frac{\partial}{\partial p}\, p^{n_1}, \tag{6}$$

so

$$\langle n_1 \rangle = \sum_{n_1=0}^{N} \frac{N!}{n_1!(N-n_1)!}\left(p\frac{\partial}{\partial p}\, p^{n_1}\right) q^{N-n_1} = p\,\frac{\partial}{\partial p} \sum_{n_1=0}^{N} \frac{N!}{n_1!(N-n_1)!}\, p^{n_1}q^{N-n_1}$$

$$= p\,\frac{\partial}{\partial p}(p+q)^N = pN(p+q)^{N-1} = pN. \qquad (7)$$

From the BINOMIAL THEOREM,

$$\langle n_2 \rangle = N - \langle n_1 \rangle = N(1-p) = qN. \qquad (8)$$

The VARIANCE is given by

$$\sigma_{n_1}^2 = \langle n_1^2 \rangle - \langle n_1 \rangle^2. \qquad (9)$$

But

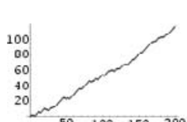
$$\langle n_1^2 \rangle = \sum_{n_1=0}^{N} \frac{N!}{n_1!(N-n_1)!}\, p^{n_1} q^{N-n_1} n_1^2, \qquad (10)$$

so

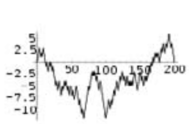
$$n_1^2 p^{n_1} = n_1 \left(p\,\frac{\partial}{\partial p} \right) p^{n_1} = \left(p\,\frac{\partial}{\partial p} \right)^2 p^{n_1}, \qquad (11)$$

and

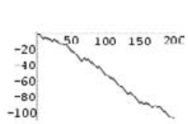
$$\begin{aligned}
\langle n_1^2 \rangle &= \sum_{n_1=0}^{N} \frac{N!}{n_1!(N-n_1)!} \left(p\,\frac{\partial}{\partial p} \right)^2 p^{n_1} q^{N-n_1} \\
&= \left(p\,\frac{\partial}{\partial p} \right)^2 \sum_{n_1=0}^{N} \frac{N!}{n_1!(N-n_1)!}\, p^{n_1} q^{N-n_1} \\
&= \left(p\,\frac{\partial}{\partial p} \right)^2 (p+q)^N \\
&= p\,\frac{\partial}{\partial p}[pN(p+q)^{N-1}] \\
&= p[N(p+q)^{N-1} + pN(N-1)(p+q)^{N-2}] \\
&= p[N + pN(N-1)] \\
&= pN[1 + pN - p)] = (Np)^2 + Npq \\
&= \langle n_1 \rangle^2 + Npq. \qquad (12)
\end{aligned}$$



Therefore,



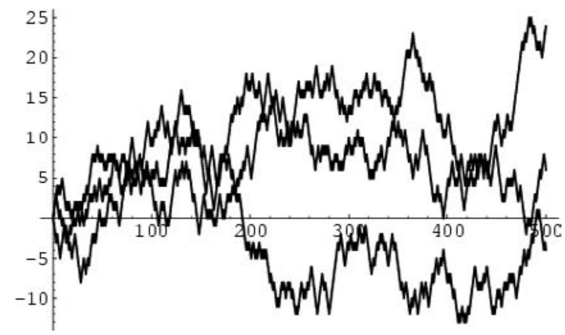
$$\sigma_{n_1}^2 = \langle n_1^2 \rangle - \langle n_1 \rangle^2 = Npq, \qquad (13)$$



and the ROOT-MEAN-SQUARE deviation is

$$\sigma_{n_1} = \sqrt{Npq}. \qquad (14)$$

For a large number of total steps N, the BINOMIAL DISTRIBUTION characterizing the distribution approaches a GAUSSIAN DISTRIBUTION.



Consider now the distribution of the distances d_N traveled after a given number of steps,

$$d_N \equiv n_1 - n_2 = 2n_1 - N, \qquad (15)$$

as opposed to the *number* of steps in a given direction. The above plots show $d_N(p)$ for $N = 200$ and three values $p = 0.1$, $p = 0.5$, and $p = 0.9$, respectively. Clearly, weighting the steps toward one direction or the other influences the overall trend, but there is still a great deal of random scatter, as emphasized by the plot below, which shows three random walks all with $p = 0.5$.

Surprisingly, the most probable number of sign changes in a walk is 0, followed by 1, then 2, etc.

For a random walk with $p = 1/2$, the probability $P_N(d)$ of traveling a given distance d after N steps is given in the following table.

steps	−5	−4	−3	−2	−1	0	1	2	3	4	5
0						1					
1					$\frac{1}{2}$	0	$\frac{1}{2}$				
2				$\frac{1}{4}$	0	$\frac{2}{4}$	0	$\frac{1}{4}$			
3			$\frac{1}{8}$	0	$\frac{3}{8}$	0	$\frac{3}{8}$	0	$\frac{1}{8}$		
4		$\frac{1}{16}$	0	$\frac{4}{16}$	0	$\frac{6}{16}$	0	$\frac{4}{16}$	0	$\frac{1}{16}$	
5	$\frac{1}{32}$	0	$\frac{5}{32}$	0	$\frac{10}{32}$	0	$\frac{10}{32}$	0	$\frac{5}{32}$	0	$\frac{1}{32}$

In this table, subsequent rows are found by adding HALF of each cell in a given row to each of the two cells diagonally below it. In fact, it is simply PASCAL'S TRIANGLE padded with intervening zeros and with each row multiplied by an additional factor of 1/2. The COEFFICIENTS in this triangle are given by

$$P_N(d) = \frac{1}{2^N} \binom{N}{\frac{d+N}{2}} \qquad (16)$$

(Papoulis 1984, p. 291). The moments

$$\mu_p = \sum_{d=-N,\ -(N-2),\ \ldots,\ N} d^p P_N(d) \qquad (17)$$

of this distribution of *signed* distances are then given by

$$\mu = 0 \qquad (18)$$

$$\mu_2 = N \tag{19}$$

$$\mu_3 = 0 \tag{20}$$

$$\mu_4 = N(3N-2), \tag{21}$$

so the MEAN is $\mu = 0$, the SKEWNESS is $\gamma_1 = 0$, and the KURTOSIS is

$$\gamma_2 = \frac{\mu_4}{\mu_2^2} - 3 = -\frac{2}{N}. \tag{22}$$

The expectation value of the absolute distance after N steps is therefore given by

$$\langle d_N \rangle = \sum_{d=-N,-(N-2),\,\ldots}^{N} |d| P_N(d)$$

$$= \frac{1}{2^N} \sum_{d=-N,-(N-2),\,\ldots}^{N} \frac{|d| N!}{\left(\frac{N+d}{2}\right)!\left(\frac{N-d}{2}\right)!}. \tag{23}$$

This sum can be done symbolically by separately considering the cases N EVEN and N ODD. First, consider EVEN N so that $N \equiv 2J$. Then

$$\langle d_{2,\,J} \rangle = \frac{N!}{2^N} \left[\sum_{\substack{d=-2J,\\ -2(J-1),\,\ldots}}^{-2} \frac{|d|}{\left(\frac{2J+d}{2}\right)!\left(\frac{2J-d}{2}\right)!} + \sum_{d=0} \frac{|d|}{\left(\frac{2J+d}{2}\right)!\left(\frac{2J-d}{2}\right)!} + \sum_{d=2,\,4,\,\ldots}^{2J} \frac{|d|}{\left(\frac{2J+d}{2}\right)!\left(\frac{2J-d}{2}\right)!} \right]$$

$$= \frac{N!}{2^N} \left[\sum_{d=-J,\,-(J-1),\,\ldots}^{-1} \frac{|2d|}{\left(\frac{2J+2d}{2}\right)!\left(\frac{2J-2d}{2}\right)!} + \sum_{d=1,\,2\,\ldots}^{J} \frac{|2d|}{\left(\frac{2J+2d}{2}\right)!\left(\frac{2J-2d}{2}\right)!} \right]$$

$$= \frac{N!}{2^N} \left[2 \sum_{d=1}^{J} \frac{2d}{(J+d)!(J-d)!} \right]$$

$$= \frac{N!}{2^{N-2}} \sum_{d=1}^{J} \frac{d}{(J+d)!(J-d)!}. \tag{24}$$

But this sum can be evaluated analytically as

$$\sum_{d=1}^{J} \frac{d}{(J+d)!(J-d)!} = \frac{1}{2\Gamma(J)\Gamma(1+J)}. \tag{25}$$

Writing $J = N/2$, plugging back in, and simplifying gives

$$\langle d_{N \text{ even}} \rangle = \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{1}{2}+\frac{1}{2}N\right)}{\Gamma\left(\frac{1}{2}N\right)} = \frac{(N-1)!!}{(N-2)!!}, \tag{26}$$

where $N!!$ is the DOUBLE FACTORIAL.

Now consider N ODD, so $N \equiv 2J-1$. Then

$$\langle d_{N \text{ odd}} \rangle = \langle d_{2J-1} \rangle$$

$$= \frac{N!}{2^N} \left[\sum_{\substack{d=-(2J-1),\\ -(2J+1),\,\ldots}}^{-1} \frac{|d|}{\left(\frac{2J-1+d}{2}\right)!\left(\frac{2J-1-d}{2}\right)!} + \sum_{d=1,\,3,\,\ldots}^{2J-1} \frac{|d|}{\left(\frac{2J-1+d}{2}\right)!\left(\frac{2J-1-d}{2}\right)!} \right]$$

$$= \frac{N!}{2^{N-1}} \left[\sum_{d=1,\,3,\,\ldots}^{2J-1} \frac{d}{\left(\frac{2J-1+d}{2}\right)!\left(\frac{2J-1-d}{2}\right)!} \right]$$

$$= \frac{N!}{2^{N-1}} \left[\sum_{d=2,\,4,\,\ldots}^{2J} \frac{d-1}{\left(\frac{2J-2+d}{2}\right)!\left(\frac{2J-d}{2}\right)!} \right]$$

$$= \frac{N!}{2^{N-1}} \left[\sum_{d=1}^{J} \frac{2d-1}{(J+d-1)!(J-d)!} \right]. \tag{27}$$

But this sum can be evaluated analytically as

$$\sum_{d=1}^{J} \frac{2d-1}{(J+d-1)!(J-d)!} = \frac{1}{[\Gamma(J)]^2}. \tag{28}$$

Writing $J = (N+1)/2$, plugging back in, and simplifying gives

$$\langle d_{N \text{ odd}} \rangle = \frac{N!}{2^{N-1}\left[\Gamma\left(\frac{1}{2}+\frac{1}{2}N\right)\right]^2}$$

$$= \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{1}{2}N+1\right)}{\Gamma\left(\frac{1}{2}N+\frac{1}{2}\right)} = \frac{N!!}{(N-1)!}. \tag{29}$$

Both the EVEN and ODD solutions can be written in terms of J as

$$\langle d_J \rangle = \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(J+\frac{1}{2}\right)}{\Gamma(J)} = \frac{(2J-1)!!}{(2J-2)!!}, \tag{30}$$

or explicitly in terms of N as

$$\langle d_N \rangle = \begin{cases} \frac{(N-1)!!}{(N-2)!!} & \text{for } N \text{ even} \\ \frac{N!!}{(N-1)!!} & \text{for } N \text{ odd.} \end{cases} \tag{31}$$

The first few values of $\langle d_N \rangle$ are therefore

$$\langle d_0 \rangle = 0$$

$$\langle d_1 \rangle = \langle d_2 \rangle = 1$$

$$\langle d_3 \rangle = \langle d_4 \rangle = \tfrac{3}{2}$$

$$\langle d_5 \rangle = \langle d_6 \rangle = \tfrac{15}{8}$$

$$\langle d_7 \rangle = \langle d_8 \rangle = \tfrac{35}{16}$$

$$\langle d_9 \rangle = \langle d_{10} \rangle = \tfrac{315}{128}$$

$$\langle d_{11} \rangle = \langle d_{12} \rangle = \tfrac{693}{256}$$

$$\langle d_{13} \rangle = \langle d_{14} \rangle = \tfrac{3003}{1024}$$

(Sloane's A001803 and A046161; Abramowitz and Stegun 1972, Prévost 1933, Hughes 1995), which are also given by the GENERATING FUNCTION

$$(1-x)^{-3/2} = 1 + \tfrac{3}{2}x + \tfrac{15}{8}x^2 + \tfrac{35}{16}x^3 + \tfrac{315}{128}x^4 + \ldots. \tag{32}$$

These numbers also arise in the HEADS-MINUS-TAILS DISTRIBUTION.

Now, examine the asymptotic behavior of $\langle d_N \rangle$. The asymptotic expansion of the GAMMA FUNCTION ratio is

$$\frac{\Gamma\left(J+\frac{1}{2}\right)}{\Gamma(J)} = \sqrt{J}\left(1 - \frac{1}{8J} + \frac{1}{128J^2} + \ldots\right) \tag{33}$$

(Graham *et al.* 1994), so plugging in the expression for $\langle d_N \rangle$ gives the asymptotic series

$$\langle d_N \rangle = \sqrt{\frac{2N}{\pi}} \times \left(1 \mp \frac{1}{4N} + \frac{1}{32N^2} \pm \frac{5}{128N^3} - \frac{21}{2048N^4} \mp \ldots\right), \tag{34}$$

where the top signs are taken for N EVEN and the bottom signs for N ODD. Therefore, for large N,

$$\langle d_N \rangle \sim \sqrt{\frac{2N}{\pi}}, \tag{35}$$

which is also shown in Mosteller *et al.* (1961, p. 14).

Tóth (2000) has proven that there are no more than three most-visited sites in a simple symmetric random walk in 1-D with unit steps.

Random Walk—2-D

In a PLANE, consider a sum of N 2-D VECTORS with random orientations. Use PHASOR notation, and let the phase of each VECTOR be RANDOM. Assume N unit steps are taken in an arbitrary direction (i.e., with the angle θ uniformly distributed in $[0, 2\pi)$ and *not* on a LATTICE), as illustrated above. The position z in the COMPLEX PLANE after N steps is then given by

$$z = \sum_{j=1}^{N} e^{i\theta_j}, \tag{1}$$

which has ABSOLUTE SQUARE

$$|z|^2 = \sum_{j=1}^{N} e^{i\theta_j} \sum_{k=1}^{N} e^{-i\theta_k} = \sum_{j=1}^{N} \sum_{k=1}^{N} e^{i(\theta_j - \theta_k)}$$

$$= N + \sum_{\substack{j,\ k=1 \\ k \neq j}}^{N} e^{i(\theta_j - \theta_k)}. \tag{2}$$

Therefore,

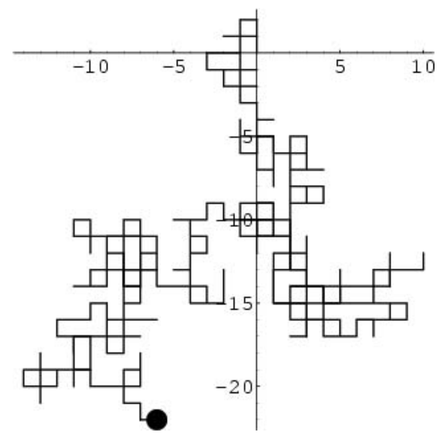
$$\left\langle |z|^2 \right\rangle = N + \left\langle \sum_{\substack{j,\ k=1 \\ k \neq j}}^{N} e^{i(\theta_j - \theta_k)} \right\rangle. \tag{3}$$

Each step is equally likely to be in any direction, so both θ_j and θ_k are RANDOM VARIABLES with identical MEANS of zero, and their difference is also a random variable. Averaging over this distribution, which has equally likely POSITIVE and NEGATIVE values yields an expectation value of 0, so

$$\left\langle |z|^2 \right\rangle = N. \tag{4}$$

The root-mean-square distance after N unit steps is therefore

$$|z|_{\text{rms}} = \sqrt{N}, \tag{5}$$



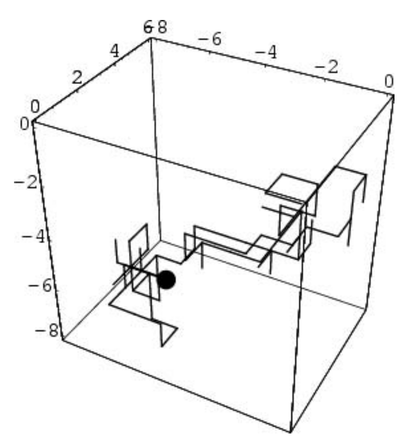
so with a step size of l, this becomes

$$d_{\text{rms}} = l\sqrt{N}. \tag{6}$$

In order to travel a distance d

$$N \approx \left(\frac{d}{l}\right)^2 \tag{7}$$

steps are therefore required.



Amazingly, it has been proven that on a 2-D LATTICE, a random walk has unity probability of reaching any point (including the starting point) as the number of steps approaches INFINITY.

Random Walk—3-D

On a 3-D LATTICE, a random walk has *less than* unity probability of reaching any point (including the starting point) as the number of steps approaches infinity. The probability of reaching the starting point

again is 0.3405373296.... This is one of PÓLYA'S RANDOM WALK CONSTANTS.

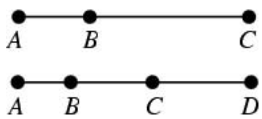
Random Young Tableau

RANDOM TABLEAU

Range (Image)



If T is a MAP (a.k.a., FUNCTION, TRANSFORMATION) over a DOMAIN D, then the range of T is defined as

$$\mathrm{Range}(T) = T(D) = \{T(\mathbf{X}) : \mathbf{X} \in D\}.$$

The range $T(D)$ is also called the IMAGE of D under T.

See also DOMAIN, MAP, TRANSFORMATION

Range (Line Segment)

A number of points on a LINE SEGMENT. The term was first used by Desargues (Cremona 1960, p. x). If the points A, B, C, ... lie on a LINE SEGMENT with the coordinates of the points such that $A < B < C$, they are said to form a range, denoted $\{ABC\ldots\}$. Let AB denote the signed distance $B - A$. Then the range $\{ABC\}$ satisfies the relation

$$AB + BC + CA = 0.$$

The range $\{ABCD\}$ satisfies

$$BC \cdot AD + CA \cdot BD + AB \cdot CD = 0$$

and

$$BC \cdot AD^2 + CA \cdot BD^2 + AB \cdot CD^2 + BC \cdot CA \cdot AB = 0,$$

the latter of which holds even when D is not on the line ABC (Lachlan 1893).

Graustein (1930) and Woods (1961) use the term "range" to refer to the totality of points on a straight LINE, making it the dual of a PENCIL.

See also AXIS, HOMOGRAPHIC, LINE, LINE SEGMENT, PENCIL, PERSPECTIVITY, SECTION (PENCIL)

Range (Statistics)

$$R \equiv \max(x_i) - \min(x_i). \tag{1}$$

For small samples, the range is a good estimator of the population STANDARD DEVIATION (Kenney and Keeping 1962, pp. 213–214). For a continuous UNIFORM DISTRIBUTION

$$P(x) = \begin{cases} \dfrac{1}{C} & \text{for } 0 < x < C \\ 0 & \text{for } |x| < C, \end{cases} \tag{2}$$

the distribution of the range is given by

$$D(R) = N\left(\frac{R}{C}\right)^{N-1} - (N-1)\left(\frac{R}{C}\right)^{N}. \tag{3}$$

Given two samples with sizes m and n and ranges R_1 and R_2, let $u \equiv R_1/R_2$. Then

$$D(u) = \begin{cases} \dfrac{m(m-1)n(n-1)}{(m+n)(m+n-1)(m+n-2)} \\ \quad \times[(m+n)u^{m-2} - (m+n-2)u^{m-1}] \\ \quad \text{for } 0 \leq u \leq 1 \\ \dfrac{m(m-1)n(n-1)}{(m+n)(m+n-1)(m+n-2)} \\ \quad \times[(m+n)u^{-n} - (m+n-2)u^{-n-1}] \\ \quad \text{for } 1 \leq u \leq \infty. \end{cases} \tag{4}$$

The MEAN is

$$\mu_u = \frac{(m-1)n}{(m+1)(n-2)}, \tag{5}$$

and the MODE is

$$\hat{u} = \begin{cases} \dfrac{(m-2)(m+n)}{(m-1)(m+n-2)} & \text{for } m - n \leq 2 \\ \dfrac{(n+1)(m+n-2)}{n(m+n)} & \text{for } m - n \geq 2. \end{cases} \tag{6}$$

Kenney, J. F. and Keeping, E. S. "The Range." §6.2 in *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, pp. 75–76, 213–214, 1962.

Rank

The word "rank" refers to several unrelated concepts in mathematics involving groups, matrices, quadratic forms, sequences, set theory, statistics, and tensors.

In SET THEORY, rank is a (class) function from SETS to ORDINAL NUMBERS. The rank of a SET is the least ORDINAL NUMBER greater than the rank of any member of the set (Mirimanoff 1917; Moore 1982, pp. 261–262; Rubin 1967, p. 214). The proof that rank is WELL DEFINED uses the AXIOM OF FOUNDATION.

For example, the EMPTY SET $\{\}$ has rank 0 (since it has no members and 0 is the least ORDINAL NUMBER), $\{\{\}\}$ has rank 1 (since $\{\}$, its only member, has rank 0), $\{\{\{\}\}\}$ has rank 2, and $\{\{\}, \{\{\}\}, \{\{\{\}\}\}, \ldots\}$ has rank ω. Every ORDINAL NUMBER has itself as its rank.

Mirimanoff (1917) showed that, assuming the class of URELEMENTS is a set, for any ORDINAL NUMBER α, the class of all sets having rank α is a SET, i.e., not a PROPER CLASS (Rubin 1967, p. 216) The number of sets having rank k for $k = 0$, 1, ... are 1, 1, 2, 12, 65520, ... (Sloane's A038081), and the number of sets having rank at most k is $\underbrace{2^{2^{\cdot^{\cdot^{2}}}}}_{k}$, 1, 2, 4, 16, 65536, ... (Sloane's A014221).

The rank of a mathematical object is defined whenever that object is FREE. In general, the rank of a FREE object is the CARDINALITY of the FREE generating SUBSET G.

Rank (Bundle)

The rank of a VECTOR BUNDLE is the DIMENSION of its FIBER. Equivalently, it is the maximum number of linearly independent LOCAL SECTIONS in a TRIVIALIZATION. Naturally, the dimension here is measured in the appropriate CATEGORY. For instance, a real line bundle has fibers isomorphic with $\mathbb{R}$, and a complex line bundle has fibers isomorphic to $\mathbb{C}$, but in both cases their rank is 1.

The rank of the TANGENT BUNDLE of a real MANIFOLD M is equal to the dimension of M. The rank of a trivial bundle $M \times \mathbb{R}^k$ is equal to k. There is no upper bound to the rank of a vector bundle over a fixed manifold M.

See also DIMENSION, FIBER, MANIFOLD, SECTION (BUNDLE), TANGENT BUNDLE, VECTOR BUNDLE

Rank (Group)

For an arbitrary finitely generated ABELIAN GROUP G, the rank of G is defined to be the rank of the FREE generating SUBSET G modulo its TORSION SUBGROUP. For a finitely generated GROUP, the rank is defined to be the rank of its "Abelianization."

See also ABELIAN GROUP, BETTI NUMBER, BURNSIDE PROBLEM, QUASITHIN THEOREM, QUASI-UNIPOTENT GROUP, TORSION (GROUP)

Rank (Matrix)

The rank of a MATRIX or a linear map is the DIMENSION of the range of the matrix or the linear map, corresponding to the number of LINEARLY INDEPENDENT rows or columns of the matrix, or to the number of nonzero singular values of the map.

Rank (Quadratic Form)

For a QUADRATIC FORM Q in the canonical form

$$Q = y_1^2 + y_2^2 + \ldots + y_p^2 - y_{p+1}^2 - y_{p+2}^2 - \ldots - y_r^2,$$

the rank is the total number r of square terms (both POSITIVE and NEGATIVE).

See also SIGNATURE (QUADRATIC FORM)

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 6th ed.* San Diego, CA: Academic Press, p. 1105, 2000.

Rank (Sequence)

The position of a RATIONAL NUMBER in the SEQUENCE $\frac{1}{1}, \frac{1}{2}, \frac{2}{1}, \frac{1}{3}, \frac{3}{1}, \frac{1}{4}, \frac{2}{3}, \frac{3}{2}, \frac{4}{1}, \frac{1}{5}$, ..., ordered in terms of increasing NUMERATOR + DENOMINATOR.

See also ENCODING, FAREY SERIES

Rank (Statistics)

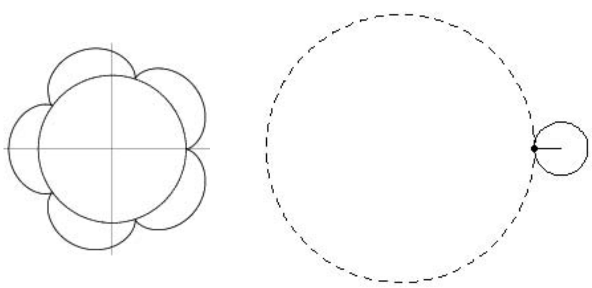
The ORDINAL NUMBER of a value in a list arranged in a specified order (usually decreasing).

See also RANK TEST, SPEARMAN RANK CORRELATION COEFFICIENT, WILCOXON RANK SUM TEST, WILCOXON SIGNED RANK TEST, ZIPF'S LAW

Rank (Tensor)

The total number of CONTRAVARIANT and COVARIANT indices of a TENSOR. The rank of a TENSOR is independent of the number of DIMENSIONS of the SPACE.

Rank	Object
0	SCALAR
1	VECTOR
≥ 2	TENSOR



See also CONTRAVARIANT TENSOR, COVARIANT TENSOR, SCALAR, TENSOR, VECTOR

Rank Test

A STATISTICAL TEST making use of the RANKS of data points. Examples include the KOLMOGOROV-SMIRNOV TEST and WILCOXON SIGNED RANK TEST.

See also KOLMOGOROV-SMIRNOV TEST, R-ESTIMATE, RANK (STATISTICS), SPEARMAN RANK CORRELATION COEFFICIENT, STATISTICAL TEST, WILCOXON SIGNED RANK TEST

Ranunculoid

An EPICYCLOID with $n=5$ cusps, named after the buttercup genus *Ranunculus* (Madachy 1979).

Rapid Rumor Ramification

GOSSIPING

RAT-Free Set

A RAT-free ("right angle triangle-free") set is a set of points, no three of which determine a RIGHT TRIANGLE. Let $f(n)$ be the largest integer such that a RAT-free subset of size $f(n)$ is guaranteed to be contained in any set of n coplanar points. Then the function $f(n)$ is bounded by

$$\sqrt{n} \leq f(n) \leq 2\sqrt{n}.$$

See also RIGHT TRIANGLE

Ratio

The ratio of two numbers r and s is written r/s, where r is the NUMERATOR and s is the DENOMINATOR. The ratio of r to s is equivalent to the QUOTIENT r/s. Betting ODDS written as $r:s$ correspond to $s/(r+s)$. A number which can be expressed as a ratio of INTEGERS is called a RATIONAL NUMBER.

See also DENOMINATOR, DIVISION, FRACTION, NUMERATOR, ODDS, QUOTIENT, RATIONAL NUMBER

Ratio Distribution

Given two distributions Y and X with joint probability density function $f(x, y)$, let $U = Y/X$ be the ratio distribution. Then the distribution function of u is

$$\begin{aligned} D(u) &= P(U \leq u) \\ &= P(Y \leq uX | X > 0) + P(Y \geq uX | X < 0) \\ &= \int_0^\infty \int_0^{ux} f(x, y)\,dy\,dx + \int_{-\infty}^0 \int_{ux}^0 f(x, y)\,dy\,dx. \end{aligned} \tag{1}$$

The probability function is then

$$\begin{aligned} P(u) = D'(u) &= \int_0^\infty x f(x, ux)\,dx - \int_{-\infty}^0 x f(x, ux)\,dx \\ &= \int_{-\infty}^\infty |x| f(x, ux)\,dx. \end{aligned} \tag{2}$$

For variates with a standard NORMAL DISTRIBUTION, the ratio distribution is a CAUCHY DISTRIBUTION. For a UNIFORM DISTRIBUTION

$$f(x, y) = \begin{cases} 1 & \text{for } x, y \in [0, 1] \\ 0 & \text{otherwise,} \end{cases} \tag{3}$$

$$P(u)=\begin{cases}0 & u<0\\ \int_0^1 x\,dx=\left[\tfrac{1}{2}x^2\right]=\tfrac{1}{2} & \text{for } 0\le u\le 1\\ \int_0^{1/u} x\,dx=\left[\tfrac{1}{2}x^2\right]_0^{1/u}=\dfrac{1}{2u^2} & \text{for } u>1.\end{cases} \quad (4)$$

See also Cauchy Distribution

Ratio Test

Let u_k be a series with positive terms and suppose

$$\rho\equiv\lim_{k\to\infty}\frac{u_{k+1}}{u_k}.$$

Then

1. If $\rho<1$, the series converges.
2. If $\rho>1$ or $\rho=\infty$, the series diverges.
3. If $\rho=1$, the series may converge or diverge.

The test is also called the Cauchy ratio test or d'Alembert ratio test.

See also Convergence Tests

Rational Approximation

If α is any number and m and n are integers, then there is a rational number m/n for which

$$\left|\alpha-\frac{m}{n}\right|\le\frac{1}{n}. \quad (1)$$

If α is irrational and k is any whole number, there is a fraction m/n with $n\le k$ and for which

$$\left|\alpha-\frac{m}{n}\right|\le\frac{1}{nk}. \quad (2)$$

Furthermore, there are an infinite number of fractions m/n for which

$$\left|\alpha-\frac{m}{n}\right|\le\frac{1}{n^2} \quad (3)$$

(Hilbert and Cohn-Vossen 1999, pp. 40–44).

Hurwitz has shown that for an irrational number ζ

$$\left|\zeta-\frac{h}{k}\right|<\frac{1}{ck^2}, \quad (4)$$

there are infinitely rational numbers h/k if $0<c\le\sqrt{5}$, but if $c>\sqrt{5}$, there are some ζ for which this approximation holds for only finitely many h/k.

See also Dirichlet's Approximation Theorem, Hurwitz's Irrational Number Theorem, Irrationality Measure, Kronecker's Approximation Theorem, Lagrange Number (Rational Approximation), Liouville's Approximation Theorem, Markov Number, Roth's Theorem, Segre's Theorem, Thue-Siegel-Roth Theorem

References

Hilbert, D. and Cohn-Vossen, S. *Geometry and the Imagination.* New York: Chelsea, p. 41, 1999.

Rational Canonical Form

Any square matrix T has a canonical form without any need to extend the field of its coefficients. For instance, if the entries of T are rational numbers, then so are the entries of its rational canonical form. (The Jordan canonical form may require complex numbers.) There exists an invertible matrix Q such that

$$\mathsf{Q}^{-1}\mathsf{T}\mathsf{Q}=\operatorname{diag}[L(\psi_1),\ L(\psi_2),\ldots,L(\psi_s)], \quad (1)$$

called the rational canonical form, where $L(f)$ is the companion matrix for the monic polynomial

$$f(\lambda)=f_0+f_1\lambda+\ldots+f_{n-1}\lambda^{n-1}+\lambda^n. \quad (2)$$

The polynomials ψ_i are called the "invariant factors" of T, and satisfy $\psi_i|\psi_{i+1}$ for $i=1$, ..., $s-1$ (Hartwig 1996). The polynomial ψ_s is the minimal polynomial and the product $\prod\psi_i$ is the characteristic polynomial of T.

The rational canonical form is unique, and shows the extent to which the minimal polynomial characterizes a matrix. For example, there is only one 6×6 matrix whose minimal polynomial is $(x^2+1)^2$, which is

$$\begin{bmatrix}0 & -1 & 0 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & -1\\ 0 & 0 & 1 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0 & -2\\ 0 & 0 & 0 & 0 & 1 & 0\end{bmatrix} \quad (3)$$

in rational canonical form.

Given a linear transformation $T:V\to V$, the vector space V becomes a $F[x]$-module, that is a module over the ring of polynomials with coefficients in the field F. The vector space determines the field F, which can be taken to be the maximal field containing the entries of a matrix for T. The polynomial x acts on a vector v by $x(v)=T(v)$. The rational canonical form corresponds to writing V as

$$F[x]/(a_1)\oplus\ldots\otimes F[x]/(a_s), \quad (4)$$

where (a_i) is the ideal generated by the invariant

FACTOR a_i in $F[x]$, the canonical form for any finitely generated module over a PRINCIPAL IDEAL RING such as $F[x]$.

More constructively, given a basis e_i for V, there is a MODULE HOMOMORPHISM

$$t : F[x]^n \to V \tag{5}$$

which is ONTO, given by

$$t\left(\sum p_i(x)e_i\right) = \sum p_i(T)e_i. \tag{6}$$

Letting K be the KERNEL,

$$V \cong F[x]^n/K. \tag{7}$$

To construct a basis for the rational canonical form, it is necessary to write K as

$$K \cong \bigoplus_{i-1}^{n-s} F[x] \oplus F[x]/(a_1) \oplus \ldots \oplus F[x](a_s), \tag{8}$$

and that is done by finding an appropriate basis for $F[x]^n$ and for K. Such a basis is found by determining matrices P and Q that are invertible $n \times n$ matrices having entries in $F[x]$ (and whose inverses are also in $F[x]$) such that

$$\mathsf{P}(x\mathsf{I} - \mathsf{T})\mathsf{Q} = \operatorname{diag}(1, \ldots, 1, a_1, \ldots, a_s), \tag{9}$$

where 1 is the IDENTITY MATRIX and $(a_1, \ldots, a_n)$ denotes a DIAGONAL MATRIX. They can be found by using ELEMENTARY MATRIX OPERATIONS.

The above matrix sends a basis for K, written as an n-tuple, to an n-tuple using a new basis f_i for $F[x]^n$, and P gives the linear transformation from the original basis to the one with the f_i. In particular,

$$K = \{\beta_1 f_1 + \ldots \beta_{n-s} f_{n-s} + \beta_{n-s+1} a_1 f_{n-s+1} + \ldots + \beta_n a_s f_n\}, \tag{10}$$

where β_i is an arbitrary polynomial in $F[x]$. Setting $z_i = P^{-1}(T)e_{n-s+i}$,

$$V = F[x]z_1 \oplus \ldots \oplus F[x]z_s. \tag{11}$$

In particular, $F[x]z_i$ is the SUBSPACE of V which is generated by $z_i, xz_i, \ldots, x^{n-1}z_i$, where n is the degree of a_i. Therefore, a basis that puts T into rational canonical form is given by

$$\{z_1, Tz_1, \ldots, T^{n_1}z_1, z_2, \ldots, T^{n_2}x_2, \ldots, T^{n_s}z_s\}. \tag{12}$$

Rational Cuboid

EULER BRICK

Rational Diagonal

NSW NUMBER

Rational Distances

It is possible to find six points in the PLANE, no three on a LINE and no four on a CIRCLE (i.e., none of which are COLLINEAR or CONCYCLIC), such that all the mutual distances are RATIONAL. An example is illustrated by Guy (1994, p. 185).

It is not known if a TRIANGLE with INTEGER sides, MEDIANS, and AREA exists (although there are incorrect PROOFS of the impossibility in the literature). However, R. L. Rathbun, A. Kemnitz, and R. H. Buchholz have showed that there are infinitely many triangles with RATIONAL sides (HERONIAN TRIANGLES) with *two* RATIONAL MEDIANS (Guy 1994, p. 188).

Rational Domain

FIELD

Rational Double Point

There are nine possible types of ISOLATED SINGULARITIES on a CUBIC SURFACE, eight of them rational double points. Each type of ISOLATED SINGULARITY

has an associated normal form and COXETER-DYNKIN DIAGRAM (A_1, A_2, A_3, A_4, A_5, D_4, D_5, E_6 and $\check{E}_6$).

The eight types of rational double points (the $\check{E}_6$ type being the one excluded) can occur in only 20 combinations on a CUBIC SURFACE (of which Fischer 1986 gives 19): A_1, $2A_1$, $3A_1$, $4A_1$, A_2, (A_2, A_1), $2A_2$, $(2A_2, A_1)$, $3A_2$, A_3, (A_3, A_1), $(A_3, 2A_1)$, A_4, (A_4, A_1), A_5, (A_5, A_1), D_4, D_5, and E_6 (Looijenga 1978, Bruce and Wall 1979, Fischer 1986).

In particular, on a CUBIC SURFACE, precisely those configurations of rational double points occur for which the disjoint union of the COXETER-DYNKIN DIAGRAM is a SUBGRAPH of the COXETER-DYNKIN DIAGRAM $\check{E}_6$. Also, a surface specializes to a more complicated one precisely when its graph is contained in the graph of the other one (Fischer 1986).

Rational Function

A QUOTIENT of two polynomials $P(z)$ and $Q(z)$,

$$R(z) \equiv \frac{P(z)}{Q(z)},$$

is called a rational function. More generally, if P and Q are POLYNOMIALS in multiple variables, their quotient is called a (multivariate) rational function.

A rational function has no singularities other than poles in the EXTENDED COMPLEX PLANE. Conversely, if a single-values function has no singularities other than poles in the EXTENDED COMPLEX PLANE, than it is a rational function (Knopp 1996, p. 137). In addition, a rational function can be decomposed into partial fractions (Knopp 1996, p. 139).

Knopp, K. "Rational Functions." §35 in *Theory of Functions Parts I and II, Two Volumes Bound as One, Part I.* New York: Dover, pp. 96 and 137–139, 1996.

Rational Integer

A synonym for INTEGER. The word "rational" is sometimes used for emphasis to distinguish it from other types of "integers" such as CYCLOTOMIC INTEGERS, EISENSTEIN INTEGERS, GAUSSIAN INTEGERS, and HAMILTONIAN INTEGERS.

See also CYCLOTOMIC INTEGER, EISENSTEIN INTEGER, GAUSSIAN INTEGER, HAMILTONIAN INTEGER, INTEGER, RATIONAL NUMBER

References

Rational Number

A number that can be expressed as a FRACTION p/q where p and q are INTEGERS and $q \neq 0$, is called a rational number with NUMERATOR p and DENOMINATOR q. Numbers which are not rational are called IRRATIONAL NUMBERS. The FIELD of rational numbers is denoted Q. Any rational number is trivially also an ALGEBRAIC NUMBER. The set of rational numbers is denoted `Rationals` in *Mathematica*, and a number x can be tested to see if it is rational using the command `Element[`x, Rationals].

Between any two members of the set of rationals, it is always possible to find another rational number. Therefore, rather counterintuitively, the rational numbers are a continuous set, but at the same time countable.

For a, b, and c any different rational numbers, then

$$\frac{1}{(a-b)^2}+\frac{1}{(b-c)^2}+\frac{1}{(c-a)^2}$$

is the SQUARE of a rational number (Honsberger 1991).

The probability that a random rational number has an EVEN DENOMINATOR is 1/3 (Salamin and Gosper 1972).

It is conjectured that if there exists a REAL NUMBER x for which both 2^x and 3^x are integers, then x is rational. This result would follow from the FOUR EXPONENTIALS CONJECTURE (Finch).

See also ALGEBRAIC INTEGER, ALGEBRAIC NUMBER, ANOMALOUS CANCELLATION, DENOMINATOR, DIRICHLET FUNCTION, FAREY SEQUENCE, FOUR EXPONENTIALS CONJECTURE, FRACTION, INTEGER, IRRATIONAL NUMBER, NUMERATOR, Q, QUOTIENT, TRANSCENDENTAL NUMBER

Rational Point

A K-rational point is a point (X, Y) on an ALGEBRAIC CURVE $f(X, Y) = 0$, where X and Y are in a FIELD K. For example, rational point in the FIELD $\mathbb{Q}$ of ordinary rational numbers is a point (X, Y) satisfying the given equation such that both X and Y are rational numbers.

The rational point may also be a POINT AT INFINITY. For example, take the ELLIPTIC CURVE

$$Y^2 = X^3 + X + 42$$

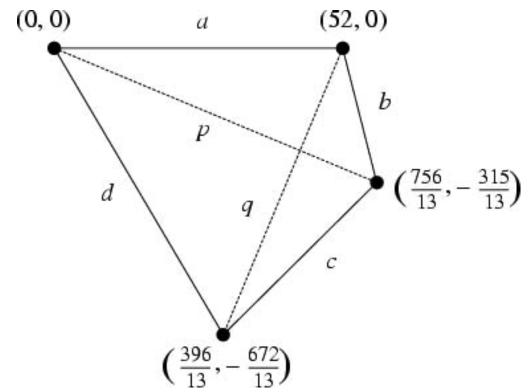
and homogenize it by introducing a third variable Z so that each term has degree 3 as follows:

$$ZY^2 = X^3 + XZ^2 + 42Z^3.$$

Now, find the points at infinity by setting $Z = 0$, obtaining

$$0 = X^3.$$

Solving gives $X = 0$, Y equal to any value, and (by definition) $Z = 0$. Despite freedom in the choice of Y, there is only a single POINT AT INFINITY because the two triples (X_1, Y_1, Z_1), (X_2, Y_2, Z_2) are considered to be equivalent (or identified) only if one is a scalar multiple of the other. Here, (0, 0, 0) is not considered to be a valid point. The triples $(a, b, 1)$ correspond to the ordinary points (a, b), and the triples $(a, b, 0)$ correspond to the POINTS AT INFINITY, usually called the LINE AT INFINITY.



The rational points on ELLIPTIC CURVES over the FINITE FIELD $GF(q)$ are 5, 7, 9, 10, 13, 14, 16, ... (Sloane's A005523).

Rational Quadrilateral

A rational quadrilateral is a QUADRILATERAL for which the sides, DIAGONALS, and AREA are RATIONAL. The simplest case has sides $a = 52$, $b = 25$, $c = 39$, and $d = 60$, DIAGONALS of length $p = 63$ and $q = 56$, and AREA 1764.

See also AREA, DIAGONAL (POLYGON), RATIONAL TRIANGLE

Rational Triangle

A rational triangle is a TRIANGLE all of whose sides are RATIONAL NUMBERS and all of whose ANGLES are RATIONAL numbers of DEGREES. The only such triangle is the EQUILATERAL TRIANGLE (Conway and Guy 1996).

Rationals

RATIONAL NUMBER

RATS Sequence

A sequence produced by the instructions "reverse, add, then sort the digits," where zeros are suppressed. For example, after 668 we get

$$668 + 866 = 1534,$$

so the next term is 1345. Applied to 1, the sequence gives 1, 2, 4, 8, 16, 77, 145, 668, 1345, 6677, 13444, 55778, ... (Sloane's A004000)

Raw Moment

A MOMENT μ_n of a probability function $P(x)$ taken about 0,

$$\mu'_n = \int x^n P(x)\, dx. \tag{1}$$

The raw moments μ'_n can be expressed as terms of the CENTRAL MOMENTS μ_n (i.e., those taken about the MEAN μ) using the inverse BINOMIAL TRANSFORM

$$\mu'_n = \sum_{k=0}^{n} \binom{n}{k} \mu_k {\mu'_1}^{n-k}, \tag{2}$$

with $\mu_0 = 1$ and $\mu_1 = 0$ (Papoulis 1984, p. 146). The first few values are therefore

$$\mu'_2 = \mu_2 + {\mu'_1}^2 \tag{3}$$

$$\mu'_3 = \mu_3 + 3\mu_2 {\mu'_1}^2 + {\mu'_1}^4 \tag{4}$$

$$\mu'_4 = \mu_4 + 4\mu_3\mu'_1 + 6\mu_2 {\mu'_1}^2 + {\mu'_1}^4 \tag{5}$$

$$\mu'_5 = \mu_5 + 5\mu_4\mu'_1 + 10\mu_3 {\mu'_1}^2 + 10\mu_2 {\mu'_1}^3 + {\mu'_1}^5. \tag{6}$$

Ray

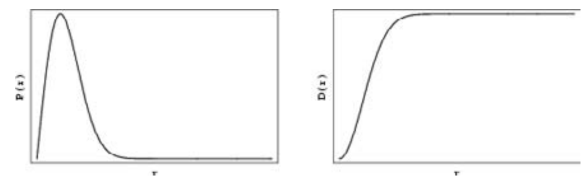
A VECTOR $\overrightarrow{AB}$ from a point A to a point B. In GEOMETRY, a ray is usually taken as a half-infinite LINE with one of the two points A and B taken to be at INFINITY.

See also LINE, VECTOR

Rayleigh Differential Equation

$$y'' - \mu\left(1 - \tfrac{1}{3} y'^2\right) y' + y = 0,$$

where $\mu > 0$. Differentiating and setting $y = y'$ gives the VAN DER POL EQUATION. The equation



$$y'' - \mu(1 - y'^2) y' + y = 0$$

with the 1/3 replaced by 1 is sometimes also called the Rayleigh differential equation (Birkhoff and Rota 1978, p. 134; Zwillinger 1997, p. 126).

See also RAYLEIGH WAVE EQUATION, VAN DER POL EQUATION

References
Birkhoff, G. and Rota, G.-C. *Ordinary Differential Equations, 3rd ed.* New York: Wiley, p. 134, 1978.
Zwillinger, D. *Handbook of Differential Equations, 3rd ed.* Boston, MA: Academic Press, p. 126, 1997.

Rayleigh Distribution

The distribution with PROBABILITY FUNCTION

$$P(r) = \frac{r e^{-r^2/2s^2}}{s^2} \tag{1}$$

for $r \in [0, \infty)$. The MOMENTS about 0 are given by

$$\mu'_m \equiv \int_0^\infty r^m P(r)\, dr = s^{-2} \int_0^\infty r^{m+1} e^{-r^2/2s^2}\, dr$$

$$= s^{-2} I_{m+1}\left(\frac{1}{2s^2}\right), \tag{2}$$

where $I(x)$ is a GAUSSIAN INTEGRAL (Papoulis 1984, p. 148). The first few of these are

$$I_1(a^{-1}) = \tfrac{1}{2} a \tag{3}$$

$$I_2(a^{-1}) = \tfrac{1}{4} a \sqrt{a\pi} \tag{4}$$

$$I_3(a^{-1}) = \tfrac{1}{2} a^2 \tag{5}$$

$$I_4(a^{-1}) = \tfrac{3}{8} a^2 \sqrt{a\pi} \tag{6}$$

$$I_5(a^{-1}) = a^3, \tag{7}$$

so the RAW MOMENTS are

$$\mu'_0 = s^{-2} \tfrac{1}{2}(2s^2) = 1 \tag{8}$$

$$\mu'_1 = s^{-2}\, \tfrac{1}{4}(2s^2)\sqrt{2s^2\pi} = \tfrac{1}{2} s\sqrt{2\pi} = s\sqrt{\frac{\pi}{2}} \tag{9}$$

$$\mu'_2 = s^{-2}\, \tfrac{1}{2}(2s^2)^2 = 2s^2 \tag{10}$$

$$\mu'_3 = s^{-2}\, \tfrac{3}{8}(2s^2)^2\sqrt{2s^2\pi} = \tfrac{3}{2} s^3\sqrt{2\pi} = 3s^3\sqrt{\frac{\pi}{2}} \tag{11}$$

$$\mu'_4 = s^{-2}(2s^2) = 8s^4. \tag{12}$$

The CENTRAL MOMENTS are therefore

$$\mu_2 = \mu_2' - (\mu_1')^2 = \frac{4-\pi}{2} s^2 \quad (13)$$

$$\mu_3 = \mu_3' - 3\mu_2'\mu_1' + 2(\mu_1')^3 = \sqrt{\frac{\pi}{2}}(\pi - 3)s^3 \quad (14)$$

$$\mu_4 = \mu_4' - 4\mu_3'\mu_1' + 6\mu_2'(\mu_1')^2 - 3(\mu - 1')^4$$
$$= \frac{32 - 3\pi^2}{4} s^4, \quad (15)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \mu_1' = s\sqrt{\frac{\pi}{2}} \quad (16)$$

$$\sigma^2 = \mu_2 = \frac{4-\pi}{2} s^2 \quad (17)$$

$$\gamma_1 = \frac{\mu_3}{\sigma_3} = \frac{2(\pi - 3)\sqrt{\pi}}{(4-\pi)^{3/2}} \quad (18)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = -\frac{6\pi^2 - 24\pi + 16}{(\pi - 4)^2}. \quad (19)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = 1 - \sqrt{\frac{\pi}{2}} ste^{-s^2t^2/2}\left[\operatorname{erfi}\left(\frac{st}{\sqrt{2}}\right) - i\right]. \quad (20)$$

Rayleigh Function

The Rayleigh functions $\sigma_n(\nu)$ for $n = 1, 2, \ldots$, are defined as

$$\sigma_n(\nu) = \sum_{k=1}^{\infty} j_{\nu k}^{-2n},$$

where $\pm j_\nu k$ are the zeros of the BESSEL FUNCTION OF THE FIRST KIND $J_\nu(z)$ (Watson 1966, p. 502; Gupta and Muldoon 1999). They were used by Euler, Rayleigh, and others to evaluate zeros of Bessel functions.

There is a convolution formula connecting Rayleigh functions of different orders,

$$\sigma_n(\nu) = \frac{1}{\nu + n} \sum_{k=1}^{n-1} \sigma_k(\nu)\sigma_{n-k}(\nu)$$

(Kishore 1963, Gupta and Muldoon 1999).

See also BESSEL FUNCTION OF THE FIRST KIND

Rayleigh-Ritz Variational Technique

A technique for computing EIGENFUNCTIONS and EIGENVALUES. It proceeds by requiring

$$J = \int_a^b [p(x)y_x^2 - q(x)y^2]\, dx \quad (1)$$

to have a STATIONARY VALUE subject to the normalization condition

$$\int_a^b y^2 w(x)\, dx = 1 \quad (2)$$

and the boundary conditions

$$py_x y|_a^b = 0. \quad (3)$$

This leads to the STURM-LIOUVILLE EQUATION

$$\frac{d}{dx}\left(p\frac{dy}{dx}\right) + qy + \lambda wy = 0, \quad (4)$$

which gives the stationary values of

$$F[y(x)] = \frac{\int_a^b (py_x^2 - qy^2)\, dx}{\int_a^b y^2 w\, dx} \quad (5)$$

as

$$F[y_n(x)] = \lambda_n, \quad (6)$$

where λ_n are the EIGENVALUES corresponding to the EIGENFUNCTION y_n.

Rayleigh's Theorem

PARSEVAL'S THEOREM

R-Bar

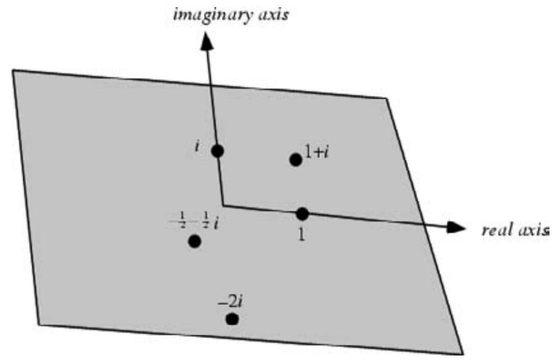
The set of affine EXTENDED REAL NUMBERS.

See also EXTENDED REAL NUMBER (AFFINE)

Re

REAL PART

Real Analysis



That portion of mathematics dealing with functions of real variables. While this includes some portions of TOPOLOGY, it is most commonly used to distinguish that portion of CALCULUS dealing with real as opposed to COMPLEX NUMBERS.

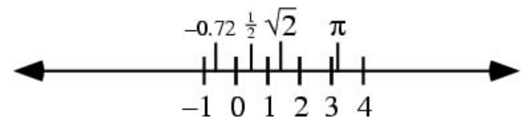
Real Analytic Function

A REAL FUNCTION is said to be analytic if it possesses derivatives of all orders and agrees with its TAYLOR SERIES in the neighborhood of every point.

See also ANALYTIC FUNCTION

Real Axis

The axis in the COMPLEX PLANE corresponding to zero IMAGINARY PART, $\Im[z] = 0$.



See also COMPLEX PLANE, IMAGINARY AXIS, REAL LINE

Real Function

A FUNCTION whose RANGE is in the REAL NUMBERS is said to be a real function, also called a real-valued function.

See also COMPLEX FUNCTION, SCALAR FUNCTION, VECTOR FUNCTION

Real Line

A LINE with a fixed scale so that every REAL NUMBER corresponds to a unique POINT on the LINE. The generalization of the real line to 2-D is called the COMPLEX PLANE.

The term "real line" is also used to distinguish an ordinary LINE from a so-called IMAGINARY LINE which can arise in algebraic geometry.

See also ABSCISSA, COMPLEX PLANE, IMAGINARY AXIS, IMAGINARY LINE, LINE, MOAT-CROSSING PROBLEM, REAL AXIS, REAL SPACE

References

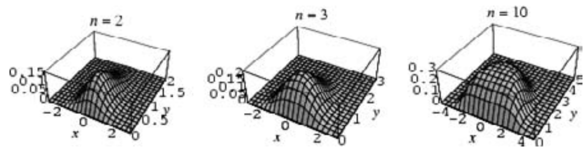
Real Manifold

See also COMPLEX MANIFOLD, MANIFOLD

Real Matrix

A real matrix is a MATRIX whose elements consist entirely of REAL NUMBERS. The set of $m \times n$ real

matrices is sometimes denoted $\mathbb{R}^{m \times n}$ (Zwillinger 1995, p. 116).



For a real $n \times n$ matrix, the expected number of real EIGENVALUES is given by

$$E_n = \begin{cases} \sqrt{2} \sum_{k=0}^{n/2-1} \frac{(4k-1)!!}{(4k)!!} & \text{for } n \text{ even} \\ 1 + \sqrt{2} \sum_{k=1}^{(n-1)/2} \frac{(4k-3)!!}{(4k-2)!!} & \text{for } n \text{ odd} \end{cases} \quad (1)$$

(Edelman *et al.* 1994, Edelman and Kostlan 1994), which has asymptotic behavior

$$E_n \sim \sqrt{\frac{2n}{\pi}}. \quad (2)$$

GIRKO'S CIRCULAR LAW considers EIGENVALUES λ (possibly complex) of a set of random $n \times n$ REAL MATRICES with entries independent and taken from a standard normal distribution. Then as $n \to \infty$, $\lambda/\sqrt{n}$ is uniformly distributed on the UNIT DISK in the COMPLEX PLANE.

Edelman (1997) proved that the density of a random *complex* pair of eigenvalues $x \pm iy$ of a real $n \times n$ matrix whose elements are taken from a standard normal distribution is

$$\rho_n(x, y) = \sqrt{\frac{2}{\pi}} y e^{y^2 - x^2} \operatorname{erfc}\left(\sqrt{2} y\right) e_{n-2}(x^2 + y^2)$$

$$= \sqrt{\frac{2}{\pi}} e^{2y^2} y \operatorname{erfc}(\sqrt{2} y) \frac{\Gamma(n-1, x^2 + y^2)}{\Gamma(n-1)} \quad (3)$$

for $y \geq 0$, where $\operatorname{erfc}(z)$ is the ERFC (complementary error) function, $e_n(z)$ is the EXPONENTIAL SUM FUNCTION, and $\Gamma(a, x)$ is the upper INCOMPLETE GAMMA FUNCTION. Integrating over the UPPER HALF-PLANE gives half the expected number of complex eigenvalues

$$\int_{-\infty}^{\infty} \int_0^{\infty} \rho_n(x, y)\, dy\, dx = 1 - 2^{n(1-n)/4}. \quad (4)$$

Real Measure

A MEASURE that takes on real values.

See also MEASURE

Real Normed Algebra

A finite dimensional ALGEBRA A containing a copy of the reals is a real algebra. Note that this implies that A must be a real VECTOR SPACE. A real normed algebra is a real algebra A with a norm that is preserved by multiplication, i.e., $|a * b| = |a||b|$.

For example, the REAL NUMBERS, the COMPLEX NUMBERS, the QUATERNIONS, and the OCTONIONS are real normed algebras. Multiplication need not be commutative in a real normed algebra (e.g., QUATERNIONS and OCTONIONS are noncommutative), nor does it even need to be associative (e.g., the OCTONIONS).

A real normed algebra A satisfies a number of algebraic restrictions. For example, if the dimension of A is greater than 1, it must contain a copy of the complex numbers. Similarly, if the dimension is greater than 2, it must contain a copy of the QUATERNIONS. And if it is greater than 4, it must contain the OCTONIONS. In fact, these are the only examples, as the OCTONIONS cannot be "doubled" to make a normed algebra.

See also ALGEBRA, COMPLEX NUMBER, OCTONION, QUATERNION, REAL NUMBER, VECTOR SPACE

Real Number

The FIELD of all RATIONAL and IRRATIONAL numbers is called the real numbers, or simply the "reals," and denoted $\mathbb{R}$. The set of real numbers is also called the CONTINUUM, denoted C. The set of reals is called `Reals` in *Mathematica*, and a number x can be tested to see if it is a member of the reals using the command `Element[`x`, Reals]`.

The real numbers can be extended with the addition of the IMAGINARY NUMBER i, equal to $\sqrt{-1}$. Numbers OF THE FORM $x + iy$, where x and y are both real, are called COMPLEX NUMBERS, which also form a FIELD. Another extension which includes both the real

numbers and the infinite ORDINAL NUMBERS of Georg Cantor is the SURREAL NUMBERS.

Plouffe's "Inverse Symbolic Calculator" includes a huge database of 54 million real numbers which are algebraically related to fundamental mathematical constants and functions.

Real Number Picking

Pick two real numbers x and y at random in (0, 1) with a UNIFORM DISTRIBUTION. What is the PROBABILITY P_{even} that $[x/y]$, where $[r]$ denotes NEAREST INTEGER FUNCTION, is EVEN? The answer may be found as follows.

$$P\left(a<\frac{x}{y}<b\right)=\begin{cases}P(ay<x<by) & \text{for } 0\le a<b<1\\ P\left(\frac{x}{b}<y<\frac{x}{a}\right) & \text{for } 1<a<b\end{cases}$$

$$=\begin{cases}\int_0^1\int_{ay}^{by}dx\,dy=\tfrac{1}{2}(b-a) & \text{for } 0\le a<b<1\\ \int_0^1\int_{x/b}^{x/a}dy\,dx=\frac{1}{2a}-\frac{1}{2b} & \text{for } 1<a<b\end{cases} \tag{1}$$

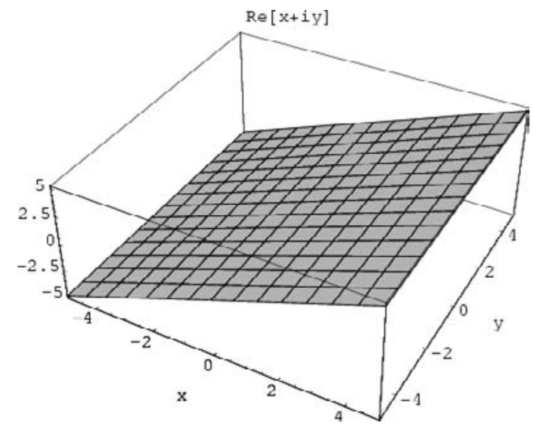
so

$$P_{\text{even}}=P\left(0<\frac{x}{y}<\tfrac{1}{2}\right)+\sum_{n=1}^{\infty}P\left(2n-\tfrac{1}{2}<\frac{x}{y}<2n+\tfrac{1}{2}\right)$$

$$=\tfrac{1}{2}\left(\tfrac{1}{2}-0\right)+\sum_{n=1}^{\infty}\left[\frac{1}{2\left(2n-\frac{1}{2}\right)}-\frac{1}{2\left(2n+\frac{1}{2}\right)}\right]$$

$$=\tfrac{1}{4}+\sum_{n=1}^{\infty}\left(\frac{1}{4n-1}+\frac{1}{4n-1}\right)$$

$$=\tfrac{1}{4}+\left(\tfrac{1}{3}-\tfrac{1}{5}+\tfrac{1}{7}-\tfrac{1}{9}+\ldots\right)=\tfrac{1}{4}+(1-\tan^{-1}1)$$



$$=\frac{5}{4}-\frac{\pi}{4}=\tfrac{1}{4}(5-\pi)\approx 46.460\% \tag{2}$$

(Putnam Exam).

Putnam Exam. Problem B-3 in the 54th Putnam Exam.

Real Part

The real part $\Re[z]$ of a COMPLEX NUMBER $z=x+iy$ is the REAL NUMBER *not* multiplying I, so $\Re[x+iy]=x$. In terms of z itself,

$$\Re[z]=\tfrac{1}{2}(z+\bar{z}),$$

where $\bar{z}$ is the COMPLEX CONJUGATE of z. The real part is implemented in *Mathematica* as `Re[z]`.

Real Projective Plane

real projective plane

The closed topological MANIFOLD, denoted $\mathbb{R}P^2$, which is obtained by projecting the points of a plane E from a fixed point P (not on the plane), with the addition of

the LINE AT INFINITY, is called the real projective plane. There is then a one-to-one correspondence between points in E and lines through P. Since each line through P intersects the sphere $\mathbb{S}^2$ centered at P and tangent to E in two ANTIPODAL POINTS, $\mathbb{R}P^2$ can be described as a QUOTIENT SPACE of $\mathbb{S}^2$ by identifying any two such points. The real projective plane is a NONORIENTABLE SURFACE.

The BOY SURFACE, CROSS-CAP, and ROMAN SURFACE are all homeomorphic to the real projective plane and, because $\mathbb{R}P^2$ is nonorientable, these surfaces contain self-intersections (Kuiper 1961, Pinkall 1986).

REAL FUNCTION

Rearrangement Theorem

Each row and each column in the GROUP multiplication table lists each of the GROUP elements once and only once. From this, it follows that no two elements may be in the identical location in two rows or two columns. Thus, each row and each column is a rearranged list of the GROUP elements. Stated otherwise, given a GROUP of n distinct elements $(I, a, b, c, \ldots, n)$, the set of products $(aI, a^2, ab, ac, \ldots, an)$ reproduces the n original distinct elements in a new order.

See also GROUP

Reciprocal

The reciprocal of a REAL or COMPLEX NUMBER $z \neq 0$ is its MULTIPLICATIVE INVERSE $1/z$. The reciprocal of a COMPLEX NUMBER $z = x + iy$ is given by

$$\frac{1}{x+iy} = \frac{x-iy}{x^2+y^2} = \frac{x}{x^2+y^2} - \frac{y}{x^2+y^2} i.$$

Given a geometric figure consisting of an assemblage of points, the POLARS with respect to an INVERSION CIRCLE constitute another figure. These figures are said to be reciprocal with respect to each other. Then there exists a DUALITY PRINCIPLE which states that theorems for the original figure can be immediately applied to the reciprocal figure after suitable modification (Lachlan 1893).

See also INVERSION, POLAR, POLE (INVERSION), RECIPROCAL CURVE, RECIPROCATION

Reciprocal Curve

The reciprocal curve of a given circle is the LOCUS of a point which moves so that its distance from the center of reciprocation varies as its distance from the line which is the reciprocal of the center of the given

circle. The reciprocal of a circle is therefore a CONIC SECTION whose FOCUS is the center of reciprocation and whose directrix is the line which corresponds to the center of reciprocation. The conic will be an ELLIPSE, HYPERBOLA, or PARABOLA if the center of reciprocation lies inside, outside, or on the given circle, respectively (Lachlan 1893, p. 181).

Reciprocal Difference

The reciprocal differences are closely related to the DIVIDED DIFFERENCE. The first few are explicitly given by

$$\rho(x_0,\ x_1)=\frac{x_0-x_1}{f_0-f_1} \tag{1}$$

$$\rho_2(x_0,\ x_1,\ x_2)=\frac{x_0-x_2}{\rho(x_0,\ x_1)-\rho(x_1,\ x_2)}+f_1 \tag{2}$$

$$\rho_3(x_0,\ x_1,\ x_2,\ x_3) = \frac{x_0-x_3}{\rho_2(x_0,\ x_1,\ x_2)-\rho_2(x_1,\ x_2,\ x_3)}+\rho(x_1,\ x_2) \tag{3}$$

$$\rho_n(x_0,\ x_1,\ \ldots,\ x_n) = \frac{x_0-x_n}{\rho_{n-1}(x_0,\ \ldots,\ x_{n-1})-\rho_{n-1}(x_1,\ \ldots\ x_n)} +\rho_{n-x}(x_1,\ \ldots,\ x_{n-1}). \tag{4}$$

Reciprocating Sphere

MIDSPHERE

Reciprocation

An incidence-preserving transformation in which points are transformed into their POLARS. A PROJECTIVE GEOMETRY-like DUALITY PRINCIPLE holds for reciprocation which states that theorems for the original figure can be immediately applied to the RECIPROCAL figure after suitable modification (Lachlan 1893, pp. 174–182). Reciprocation (or "polar reciprocation") is the strictly proper term for duality. Brückner (1900) gave one the first exact definitions of polar reciprocation for constructing DUAL POLYHEDRA, although the plane geometric version (POLE, POLAR, and POWER of a circle) was considered by none less than Euclid (Wenninger 1983, pp. 1–2).

Lachlan 1893 (pp. 257–265) discusses another type of reciprocation he terms "circular reciprocation." However, the circular reciprocal figure is, in general, more complicated than the original, so the method is not as powerful as the usual polar reciprocation.

Reciprocity Law

RECIPROCITY THEOREM

Reciprocity Theorem

If there exists a RATIONAL INTEGER x such that, when n, p, and q are POSITIVE INTEGERS,

$$x^n \equiv q \pmod{p},$$

then q is the n-adic residue of p, i.e., q is an n-adic residue of p IFF $x^n \equiv q \pmod{p}$ is solvable for x. Reciprocity theorems relate statements OF THE FORM "p is an n-adic residue of q" with reciprocal statements of the form "q is an n-adic residue of p."

The first case to be considered was $n = 2$ (the QUADRATIC RECIPROCITY THEOREM), of which Gauss gave the first correct proof. Gauss also solved the case $n = 3$ (CUBIC RECIPROCITY THEOREM) using INTEGERS OF THE FORM $a + b\rho$, where ρ is a root of $x^2 + x + 1 = 0$ and a, b are rational INTEGERS. Gauss stated the case $n = 4$ (BIQUADRATIC RECIPROCITY THEOREM) using the GAUSSIAN INTEGERS.

Proof of n-adic reciprocity for PRIME n was given by Eisenstein in 1844–50 and by Kummer in 1850–61. In the 1920s, Artin formulated ARTIN'S RECIPROCITY THEOREM, a general reciprocity law for all orders.

Recognize

LATTICE REDUCTION

Recontres Problem

DERANGEMENT

Rectangle

A closed planar QUADRILATERAL with opposite sides of equal lengths a and b, and with four RIGHT ANGLES. The AREA of the rectangle is

$$A = ab,$$

and its DIAGONALS p and q are of length

$$p = q = \sqrt{a^2 + b^2}.$$

A SQUARE is a degenerate rectangle with $a = b$.

A number of important topological surfaces can be constructed from the rectangle. Gluing both pairs of opposite edges together with no twists gives a TORUS, gluing two opposite edges together after giving a half-twist gives a MÖBIUS STRIP, gluing both pairs of opposite edges together giving one pair a half-twist gives a KLEIN BOTTLE, and giving both pairs a half-twist gives a PROJECTIVE PLANE (Stewart 1997).

Rectangle Function

The rectangle function $\Pi(x)$ is a function which is 0 outside the interval $[-1/2,\ 1/2]$ and unity inside it. It is also called the GATE FUNCTION, PULSE FUNCTION, or

WINDOW FUNCTION, and is defined by

$$\Pi(x) \equiv \begin{cases} 0 & \text{for } |x| > \frac{1}{2} \\ \frac{1}{2} & \text{for } |x| = \frac{1}{2} \\ 1 & \text{for } |x| < \frac{1}{2}. \end{cases} \tag{1}$$

The function $f(x) = h\Pi((x-c)/b)$ has height h, center c, and full-width b. Identities satisfied by the rectangle function include

$$\Pi(x) = H\left(x+\tfrac{1}{2}\right) - H\left(x-\tfrac{1}{2}\right) \tag{2}$$

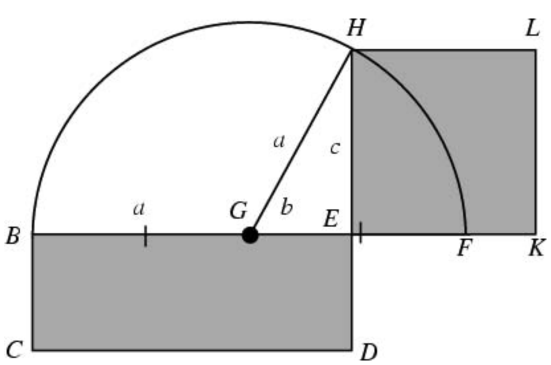
$$= H\left(\tfrac{1}{2}+x\right) + H\left(\tfrac{1}{2}-x\right) - 1 \tag{3}$$

$$= H\left(\tfrac{1}{4}-x^2\right) \tag{4}$$

$$= \tfrac{1}{2}\left[\operatorname{sgn}\left(x+\tfrac{1}{2}\right) - \operatorname{sgn}\left(x-\tfrac{1}{2}\right)\right], \tag{5}$$

where $H(x)$ is the HEAVISIDE STEP FUNCTION. The FOURIER TRANSFORM of the rectangle function is given by

$$\mathcal{F}[\Pi(x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx}\Pi(x)\,dx = \operatorname{sinc}(\pi k), \tag{6}$$



where $\operatorname{sinc}(x)$ is the SINC FUNCTION.

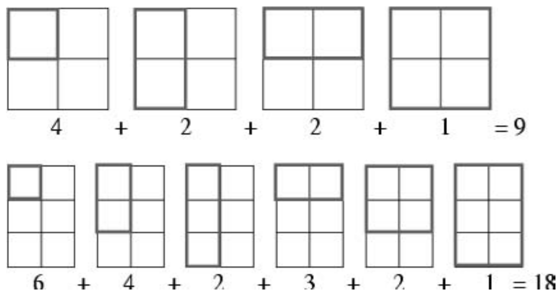
Rectangle Squaring

Given a RECTANGLE $\square BCDE$, draw $EF = DE$ on an extension of BE. Bisect BF and call the MIDPOINT G. Now draw a SEMICIRCLE centered at G, and construct the extension of ED which passes through the SEMICIRCLE at H. Then $\square EKLH$ has the same AREA as $\square BCDE$. This can be shown as follows:



$$A(\square BCDE) = BE \cdot ED = BE \cdot EF$$

$$(a+b)(a-b) = a^2 - b^2 = c^2.$$

References

Dunham, W. "Hippocrates' Quadrature of the Lune." Ch. 1 in *Journey through Genius: The Great Theorems of Mathematics.* New York: Wiley, pp. 13–14, 1990.

Rectangle Tiling

The number of ways $N(m, n)$ in which an $m \times n$ RECTANGLE can be tiled into subrectangles can be computed by counting the number of ways in which the upper right-hand corner can be selected for a given lower left-hand corner. For a lower left-hand corner with coordinates (i, j), there are $(m-i)(n-j)$ possible upper right-hand corners, so

$$N(m, n) = \sum_{i=0}^{m-1} \sum_{j=0}^{n-1} (m-i)(n-j) = \tfrac{1}{4}m(m+1)n(n+1).$$

Equivalently, $N(m, n)$ is the number of ways of picking two lines out of sets of $m+1$ and $n+1$ lines, giving

$$N(m, n) = \binom{m+1}{2}\binom{n+1}{2} = \tfrac{1}{4}m(m+1)n(n+1),$$

as before. Particular tilings are shown above for 2×2 and 2×3 rectangles.

Rectangular Coordinates

CARTESIAN COORDINATES

Rectangular Distribution

UNIFORM DISTRIBUTION

Rectangular Hyperbola

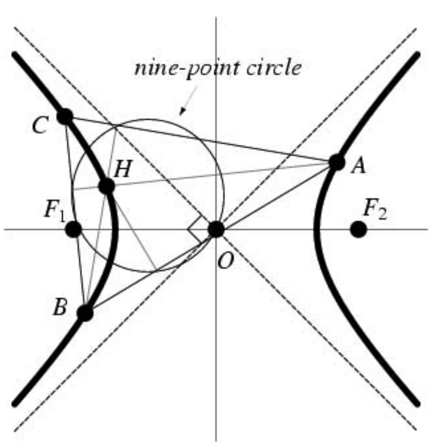
rectangular hyperbola

A HYPERBOLA for which the ASYMPTOTES are PERPENDICULAR, also called an EQUILATERAL HYPERBOLA or RIGHT HYPERBOLA. This occurs when the SEMIMAJOR and SEMIMINOR AXES are equal. This corresponds to taking $a = b$, giving eccentricity $e = \sqrt{2}$. Plugging $a = b$ into the general equation of a HYPERBOLA with SEMIMAJOR AXIS parallel to the X-AXIS and SEMIMINOR AXIS parallel to the Y-AXIS (i.e., vertical DIRECTRIX),

$$\frac{(x - x_0)^2}{a^2} - \frac{(y - y_0)^2}{b^2} = 1 \tag{1}$$

therefore gives

$$(x - x_0)^2 - (y - y_0)^2 = a^2. \tag{2}$$



The rectangular hyperbola opening to the left and right has polar equation

$$r^2 = a^2 \sec(2\theta), \tag{3}$$

and the rectangular hyperbola opening in the first and third quadrants has the Cartesian equation

$$xy = a^2. \tag{4}$$

The INVERSE CURVE of a rectangular hyperbola with INVERSION CENTER at the center of the hyperbola is a LEMNISCATE (Wells 1991).

If the three vertices of a TRIANGLE ΔABC lie on a rectangular hyperbola, then so does the ORTHOCENTER H (Wells 1991). Equivalently, if four points form an ORTHOCENTRIC SYSTEM, then there is a family of rectangular hyperbolas through the points. Moreover, the LOCUS of centers O of these hyperbolas is the NINE-POINT CIRCLE of the triangle (Wells 1991).

If four points do not form an ORTHOCENTRIC SYSTEM, then there is a unique rectangular hyperbola passing through them, and its center is given by the intersection of the NINE-POINT CIRCLES of the points taken three at a time (Wells 1991).

See also HYPERBOLA, LEMNISCATE, NINE-POINT CIRCLE, ORTHOCENTRIC SYSTEM

Rectangular Projection

EQUIRECTANGULAR PROJECTION

Rectifiable Current

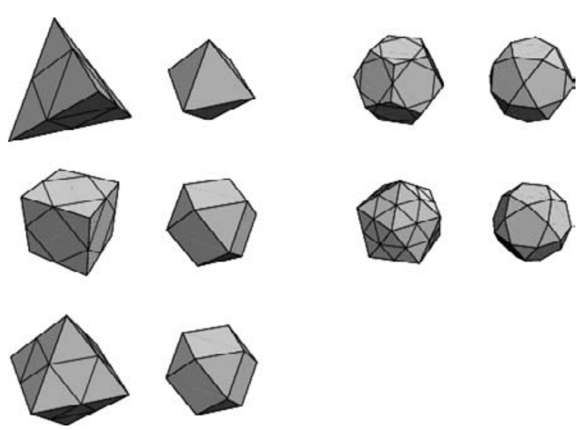
The space of currents arising from rectifiable sets by integrating a differential form is called the space of 2-D rectifiable currents. For C a closed bounded rectifiable curve of a number of components in $\mathbb{R}^3$, C bounds a rectifiable current of least AREA. The theory of rectifiable currents generalizes to m-D surfaces in $\mathbb{R}^n$.

See also INTEGRAL CURRENT, REGULARITY THEOREM

References

Morgan, F. "What is a Surface?" *Amer. Math. Monthly* **103**, 369–376, 1996.

Rectifiable Set



The rectifiable sets include the image of any LIPSCHITZ FUNCTION f from planar domains into $\mathbb{R}^3$. The full set is obtained by allowing arbitrary measurable subsets of countable unions of such images of Lipschitz functions as long as the total AREA remains finite. Rectifiable sets have an "approximate" tangent plane at almost every point.

References

Morgan, F. "What is a Surface?" *Amer. Math. Monthly* **103**, 369–376, 1996.

Rectification

The term rectification is sometimes used to refer to the determination of the length of a curve.

Rectification also refers to the operation which converts the midpoints of the edges of a regular polyhedron to the vertices of the related "rectified" polyhedron. Rectified forms are bounded by a combination of rectified cells and VERTEX FIGURES. Therefore, a rectified polychoron r$\{p, q, r\}$ is bounded by r$\{p, q\}s$ and $\{q, r\}s$. For example, r$\{3, 3, 5\}$ is bounded by 600 truncated tetrahedra (truncated cells) and 120 icosahedra (vertex figures). A rectified polyhedron is indicated by perpending an "r" to the Schläfli symbol.

POLYHEDRON	SCHLÄFLI SYMBOL	rectified polygon	SCHLÄFLI SYMBOL
TETRAHEDRON	$\{3, 3\}$	OCTAHEDRON	r$\{3, 3\}$ $=\{3, 4\}$
OCTAHEDRON	$\{3, 4\}$	CUBOCTAHEDRON	r$\{3, 4\}=\left\{\begin{smallmatrix}3\\4\end{smallmatrix}\right\}$
CUBE	$\{4, 3\}$	CUBOCTAHEDRON	r$\{4, 3\}=\left\{\begin{smallmatrix}3\\4\end{smallmatrix}\right\}$
ICOSAHEDRON	$\{3, 5\}$	ICOSIDODECAHEDRON	r$\{3, 5\}=\left\{\begin{smallmatrix}3\\5\end{smallmatrix}\right\}$
DODECAHEDRON	$\{5, 3\}$	ICOSIDODECAHEDRON	r$\{5, 3\}=\left\{\begin{smallmatrix}3\\5\end{smallmatrix}\right\}$
16-CELL	$\{3, 3, 4\}$	24-CELL	r$\{3, 3, 4\}$ $=\{3, 4, 3\}$

Rectification of the six regular POLYCHORA gives five (not six) new POLYCHORA since the rectified 16-CELL r$\{3, 3, 4\}$ is the 24-CELL $\{3, 4, 3\}$.

See also QUADRABLE, SQUARING, STELLATION, TRUNCATION, VERTEX FIGURE

Rectifying Latitude

An AUXILIARY LATITUDE which gives a sphere having correct distances along the meridians. It is denoted μ (or ω) and is given by

$$\mu = \frac{\pi M}{2M_p}. \tag{1}$$

M_p is evaluated for M at the north pole ($\phi = 90°$), and M is given by

$$\begin{aligned} M &= a(1-e^2)\int_0^\phi \frac{d\phi}{(1-e^2\sin^2\phi)^{3/2}} \\ &= a\left[\int_0^\phi \sqrt{1-e^2\sin^2\phi}\,d\phi - \frac{e^2\sin\phi\cos\phi}{\sqrt{1-e^2\sin^2\phi}}\right]. \end{aligned} \tag{2}$$

A series for M is

$$\begin{aligned} M = a[&(1-\tfrac{1}{4}e^2-\tfrac{3}{64}e^4-\tfrac{5}{256}e^6-\ldots)\phi \\ &-\left(\tfrac{3}{8}e^2+\tfrac{3}{32}e^4+\tfrac{45}{1024}e^6+\ldots\right)\sin(2\phi) \\ &+\left(\tfrac{15}{256}e^4+\tfrac{45}{1024}e^6+\ldots\right)\sin(4\phi) \end{aligned}$$

$$-\left(\tfrac{35}{3072}e^6+\ldots\right)\sin(6\phi)+\ldots], \quad (3)$$

and a series for μ is

$$\mu=\phi-\left(\tfrac{3}{2}e_1-\tfrac{9}{16}e_1^3+\ldots\right)\sin(2\phi)$$
$$+\left(\tfrac{15}{16}e_1^2-\tfrac{15}{32}e_1^4+\ldots\right)\sin(4\phi)$$
$$-\left(\tfrac{35}{48}e_1^3-\ldots\right)\sin(6\phi)+\left(\tfrac{315}{512}e_1^4-\ldots\right)\sin(8\phi)+\ldots, \quad (4)$$

where

$$e_1\equiv\frac{1-\sqrt{1-e^2}}{1+\sqrt{1-e^2}}. \quad (5)$$

The inverse formula is

$$\phi=\mu+\left(\tfrac{3}{2}e_1-\tfrac{27}{32}e_1^3+\ldots\right)\sin(2\mu)$$
$$+\left(\tfrac{21}{16}e_1^2-\tfrac{55}{32}e_1^4+\ldots\right)\sin(4\mu)$$
$$+\left(\tfrac{151}{96}e_1^3-\ldots\right)\sin(6\mu)$$
$$-\left(\tfrac{1097}{512}e^4-\ldots\right)\sin(8\mu)+\ldots \quad (6)$$

The PLANE spanned by the TANGENT VECTOR **T** and BINORMAL VECTOR **B**.

See also BINORMAL VECTOR, TANGENT VECTOR

Rectilinear Crossing Number

The minimum number $\bar{\nu}(G)$ of crossings in a straight line drawing of a graph G in a plane. For a COMPLETE GRAPH of order $n\geq 10$, the rectilinear crossing number is always larger than the general graph crossing number. For the COMPLETE GRAPH K_n with $n=1$, 2, ..., $\bar{\nu}(G)$ is 0, 0, 0, 0, 1, 3, 9, 19, 36, 62, ... (Sloane's A014540; White and Beineke 1978, Schneinerman and Wilf 1994). Although it had long been known that $\bar{\nu}(K_{10})$ was either 61 or 62 (Singer 1971, Gardner 1986), it was finally proven to be 62 by Brodsky *et al.* (2000).

Upper limits have been provided by Singer (1971), who showed that

$$\bar{\nu}(K_n)\leq\tfrac{1}{312}\left(5n^4-39n^3+91n^2-57n\right), \quad (1)$$

and Jensen (1971), who showed that

$$\bar{\nu}(K_n)\leq\tfrac{7}{432}n^4+\mathcal{O}\left(n^3\right). \quad (2)$$

Bounds for $\bar{\nu}(K_n)$ are given by

$$0.290<\frac{61}{210}\leq\rho=\lim_{n\to\infty}\frac{\bar{\nu}(K_n)}{\binom{n}{4}}\leq\frac{5}{13}<0.385, \quad (3)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and the exact value of ρ is not known (Finch).

The rectilinear crossing number has an unexpected connection with SYLVESTER'S FOUR-POINT PROBLEM (Finch).

Recurrence Relation

A mathematical relationship expressing f_n as some combination of f_i with $i < n$. The solutions to a linear recurrence can be computed straightforwardly, but QUADRATIC RECURRENCES are not so well understood. The sequence generated by a recurrence relation is called a RECURRENCE SEQUENCE. Perhaps the most famous example of a recurrence relation is the one defining the FIBONACCI NUMBERS,

$$F_n = F_{n-2} + F_{n-1}$$

for $n \geq 3$ and with $F_1 = F_2 = 1$.

Recurrence Sequence

A sequence of numbers generated by a RECURRENCE RELATION is called a recurrence sequence. Perhaps the most famous recurrence sequence is the FIBONACCI NUMBERS.

For a finite linear recurrence sequence of functions

$$s_i(x) = A_i(x)s_{i+1}(x) + B_i(x)$$

where $i = 1, \ldots, r-1$, and $s_r(x) = h(x)$, then

$$s_1(x) = \begin{vmatrix} B_1(x) & -A_1(x) & 0 & \ddots & 0 \\ B_2(x) & 1 & -A_2(x) & \ddots & 0 \\ B_3(x) & 0 & 1 & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ B_{r-1}(x) & 0 & 0 & \ddots & -A_{r-1}(x) \\ h(x) & 0 & 0 & \ddots & 1 \end{vmatrix} \quad (1)$$

(Mansour 2000).

If a sequence $\{x_n\}$ with $x_1 = x_2 = 1$ is described by a two-term linear RECURRENCE RELATION OF THE FORM

$$x_n = Ax_{n-1} + Bx_{n-2} \quad (2)$$

for $n \geq 3$ and A and B constants, then the closed form for x_n is given by

$$x_n = \frac{\alpha^n - \beta^n}{\alpha - \beta} \quad (3)$$

where α and β are the ROOTS of the QUADRATIC EQUATION

$$x^2 - Ax - B = 0, \quad (4)$$

$$\alpha = \tfrac{1}{2}\left(A + \sqrt{A^2 + 4B}\right) \quad (5)$$

$$\beta = \tfrac{1}{2}\left(A - \sqrt{A^2 + 4B}\right) \quad (6)$$

For example, the FIBONACCI NUMBERS F_n which are equal to 1, 1, 2, 3, 5, 8, ... for $n = 1, 2, \ldots$, have $A = B = 1$, so $\alpha = (1 + \sqrt{5})/2$ and $\beta = (1 - \sqrt{5})/2$, giving

$$F_n = \frac{\left[\tfrac{1}{2}(1 + \sqrt{5})\right]^n - \left[\tfrac{1}{2}(1 - \sqrt{5})\right]^n}{\sqrt{5}} = \frac{(1 + \sqrt{5})^n - (1 - \sqrt{5})^n}{2^n\sqrt{5}}. \quad (7)$$

Grosjean (1993) discusses how to rewrite such "difference of powers of roots" solutions in explicit integer form.

The general second-order linear recurrence

$$x_n = Ax_{n-1} + Bx_{n-2} \quad (8)$$

for constants A and B with arbitrary x_1 and x_2 has terms

$$\begin{aligned} x_1 &= x_1 \\ x_2 &= x_2 \\ x_3 &= Bx_1 + Ax_2 \\ x_4 &= Bx_2 + ABx_1 + A^2x_2 \\ x_5 &= B^2x_1 + 2ABx_2 + A^2Bx_1 + A^3x_2 \\ x_6 &= B^2x_2 + 2AB^2x_1 + 3A^2Bx_2 + A^3Bx_1 + A^4x_2 \\ x_7 &= B^3x_1 + 4A^3Bx_2 + 3A^2B^2x_1 + 3AB^2x_2 + A^4Bx_1 + A^5x_2, \end{aligned}$$

so an arbitrary term can be written as

$$x_n = \sum_{k=0}^{n-2} \binom{\left\lfloor \tfrac{1}{2}(n+k-2) \right\rfloor}{k} A^k B^{\lfloor (n-k-1)/2 \rfloor} \times x_1^{[n+k \pmod 2]} x_2^{[n+k+1 \pmod 2]}. \quad (9)$$

$$= -(Ax_1 - x_2) \sum_{k=0}^{n-2} A^{2k-n+2} B^{-k+n-2} \binom{k}{n-k-2} + x_1 \sum_{k=0}^{n-1} A^{2k-n+1} B^{-k+n-1} \binom{k}{n-k-1}. \quad (10)$$

The general linear third-order recurrence

$$x_n = Ax_{n-1} + Bx_{n-2} + Cx_{n-3} \quad (11)$$

has solution

$$x_n = x_1\left(\frac{\alpha^{-n}}{A+2\alpha B+3\alpha^2 C}+\frac{\beta^{-n}}{A+2\beta B+3\beta^2 C}\right.$$
$$\left.+\frac{\gamma^{-n}}{A+2\gamma B+3\gamma^2 C}\right)-(Ax_1-x_2)$$
$$\times\left(\frac{\alpha^{1-n}}{A+2\alpha B+3\alpha^2 C}+\frac{\beta^{1-n}}{A+2\beta B+3\beta^2 B}\right.$$
$$\left.+\frac{\gamma^{1-n}}{A+2\gamma C+3\gamma^2 C}\right)-(Bx_1+Ax_2-x_3)$$
$$\times\left(\frac{\alpha^{2-n}}{A+2\alpha B+3\alpha^2 C}+\frac{\beta^{2-n}}{A+2\beta B+3\beta^2 C}\right.$$
$$\left.+\frac{\gamma^{2-n}}{A+2\gamma B+3\gamma^2 C}\right), \qquad (12)$$

where α, β, and γ are the roots of the polynomial

$$Cx^3+Bx^2+Ax=1. \qquad (13)$$

A QUOTIENT-DIFFERENCE TABLE eventually yields a line of 0s IFF the starting sequence is defined by a linear RECURRENCE RELATION.

A linear second-order recurrence

$$f_{n+1}=xf_n+yf_{n-1} \qquad (14)$$

can be solved rapidly using a "rate doubling,"

$$f_{n+2}=(x^2+2y)f_n-y^2f_{n-2}, \qquad (15)$$

"rate tripling"

$$f_{n+3}=(x^3+3xy)f_n+y^3f_{n-3}, \qquad (16)$$

or in general, "rate k-tupling" formula

$$f_{n+k}=p_kf_n+q_kf_{n-k}, \qquad (17)$$

where

$$p_0=2 \qquad (18)$$

$$p_1=x \qquad (19)$$

$$p_k=2(-y)^{k/2}T_k(x/(2i\sqrt{y})) \qquad (20)$$

$$p_{k+1}=xp_k+yp_{k-1} \qquad (21)$$

(here, $T_k(x)$ is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND) and

$$q_0=-1 \qquad (22)$$

$$q_1=y \qquad (23)$$

$$q_k=-(-y)^k \qquad (24)$$

$$q_{k+1}=-yq_k \qquad (25)$$

(Gosper and Salamin 1972).

Let

$$s(X)=\prod_{i=1}^{m}(1-\alpha_iX)^{n_i}=1-s_1X-\ldots-s_nX^n, \qquad (26)$$

where the generalized POWER sum $a(h)$ for $h=0, 1, \ldots$ is given by

$$a(h)=\sum_{i=1}^{m}A_i(h)\alpha_i^h, \qquad (27)$$

with distinct NONZERO roots α_i, COEFFICIENTS $A_i(h)$ which are POLYNOMIALS of degree n_i-1 for POSITIVE INTEGERS n_i, and $i\in[1, m]$. Then the sequence $\{a_h\}$ with $a_h=a(h)$ satisfies the RECURRENCE RELATION

$$a_{h+n}=s_ia_{h+n-1}+\ldots+s_na_h \qquad (28)$$

(Meyerson and van der Poorten 1995).

The terms in a general recurrence sequence belong to a finitely generated RING over the INTEGERS, so it is impossible for every RATIONAL NUMBER to occur in any finitely generated recurrence sequence. If a recurrence sequence vanishes infinitely often, then it vanishes on an arithmetic progression with a common difference 1 that depends only on the roots. The number of values that a recurrence sequence can take on infinitely often is bounded by some INTEGER l that depends only on the roots. There is no recurrence sequence in which each INTEGER occurs infinitely often, or in which every GAUSSIAN INTEGER occurs (Myerson and van der Poorten 1995).

Let $\mu(n)$ be a bound so that a nondegenerate INTEGER recurrence sequence of order n takes the value zero at least $\mu(n)$ times. Then $\mu(2)=1$, $\mu(3)=6$, and $\mu(4)\geq 9$ (Myerson and van der Poorten 1995). The maximal case for $\mu(3)$ is

$$a_{n+3}=2a_{n+2}-4a_{n+1}+4a_n \qquad (29)$$

with

$$a_0=a_1=0 \qquad (30)$$

$$a_2=1. \qquad (31)$$

The zeros are

$$a_0=a_1=a_4=a_6=a_{13}=a_{52}=0 \qquad (32)$$

(Beukers 1991).

Recurring Decimal

REPEATING DECIMAL

Recurring Digital Invariant

To define a recurring digital invariant of order k, compute the sum of the kth powers of the digits of a number n. If this number n' is equal to the original number n, then $n = n'$ is called a k-NARCISSISTIC NUMBER. If not, compute the sums of the kth powers of the digits of n', and so on. If this process eventually leads back to the original number n, the *smallest number* in the sequence $\{n, n', n'', \ldots\}$ is said to be a k-recurring digital invariant. For example,

$$55 : 5^3 + 5^3 = 250$$

$$250 : 2^3 + 5^3 + 0^3 = 133$$

$$133 : 1^3 + 3^3 + 3^3 = 55,$$

so 55 is an order 3 recurring digital invariant. The following table gives recurring digital invariants of orders 2 to 10 (Madachy 1979).

Order	RDI	Cycle Lengths
2	4	8
3	55, 136, 160, 919	3, 2, 3, 2
4	1138, 2178	7, 2
5	244, 8294, 8299, 9044, 9045, 10933,	28, 10, 6, 10, 22, 4, 12, 2, 2
	24584, 58618, 89883	
6	17148, 63804, 93531, 239459, 282595	30, 2, 4, 10, 3
7	80441, 86874, 253074, 376762,	92, 56, 27, 30, 14, 21
	922428, 982108, five more	
8	6822, 7973187, 8616804	
9	322219, 2274831, 20700388, eleven more	
10	20818070, five more

Recursion

A recursive process is one in which objects are defined in terms of other objects of the same type. Using some sort of RECURRENCE RELATION, the entire class of objects can then be built up from a few initial values and a small number of rules. The FIBONACCI NUMBERS are most commonly defined recursively. Care, however, must be taken to avoid SELF-RECURSION, in which an object is defined in terms of itself, leading to an infinite nesting.

Recursive Function

A recursive function is a function generated by (1) ADDITION, (2) MULTIPLICATION, (3) selection of an element from a list, and (4) determination of the truth or falsity of the INEQUALITY $a < b$ according to the technical rules:

1. If F and the sequence of functions $G_1, ..., G_n$ are recursive, then so is $F(G_1, \ldots, G_n)$.
2. If F is a recursive function such that there is an x for each a with $H(a, x) = 0$, then the smallest x can be obtained recursively.

A TURING MACHINE is capable of computing recursive functions.

Red Net

The coloring red of two COMPLETE SUBGRAPHS of $n/2$ points (for EVEN n) in order to generate a BLUE-EMPTY GRAPH.

See also BLUE-EMPTY GRAPH, COMPLETE GRAPH

Red-Black Tree

An extended BINARY TREE satisfying the following conditions:

1. Every node has two CHILDREN, each colored either red or black.
2. Every LEAF node is colored black.
3. Every red node has both of its CHILDREN colored black.
4. Every path from the ROOT to a LEAF contains the same number (the "black-height") of black nodes.

Let n be the number of internal nodes of a red-black tree. Then the number of red-black trees for $n = 1, 2, \ldots$ is 2, 2, 3, 8, 14, 20, 35, 64, 122, ... (Sloane's A001131). The number of trees with black roots and red roots are given by Sloane's A001137 and Sloane's A001138, respectively.

Let T_h be the GENERATING FUNCTION for the number of red-black trees of black-height h indexed by the number of LEAVES. Then

$$T_{h+1}(x) = [T_h(x)]^2 + [T_h(x)]^4, \quad (1r_p ar \tag{1}$$

where $T_1(x) = x + x^2$. If $T(x)$ is the GENERATING FUNCTION for the number of red-black trees, then

$$T(x) = x + x^2 + T\left(x^2(1+x)^2\right) \tag{2}$$

(Ruskey). Let $rb(n)$ be the number of red-black trees with n LEAVES, $r(n)$ the number of red-rooted trees, and $b(n)$ the number of black-rooted trees. All three of the quantities satisfy the RECURRENCE RELATION

$$R(n) = \sum_{n/4 \le n \le n/2} \binom{2m}{n-2m} R(m), \tag{3}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, $rb(1) = 1$, $rb(2) = 2$ for $R(n) = rb(n)$, $r(1) = r(3) = 0$, $r(2) = 1$ for $R(n) = r(n)$, and $b(1) = 1$ for $R(n) = b(n)$ (Ruskey).

Reducible Crossing

reducible crossing

A crossing in a KNOT DIAGRAM for which there exists a circle in the projection plane meeting the diagram transversely at that crossing, but not meeting the diagram at any other point. Removable crossings can be removed by twisting, and so cannot occur in a KNOT DIAGRAM of minimal CROSSING NUMBER. Reducible crossings are also called nugatory crossings (Tait 1898, Hoste *et al.* 1998) or removable crossings.

Reducible Matrix

A SQUARE $n \times n$ matrix $\mathsf{A} = a_{ij}$ is called reducible if the indices 1, 2, ..., n can be divided into two disjoint nonempty sets $i_1, i_2, ..., i_\mu$ and $j_1, j_2, ..., j_\nu$ (with $\mu + \nu = n$) such that

$$a_{i_\alpha} j_\beta = 0$$

for $\alpha = 1, 2, ..., \mu$ and $\beta = 1, 2, ..., \nu$. A SQUARE MATRIX which is not reducible is said to be IRREDUCIBLE.

Reducible Representation

IRREDUCIBLE REPRESENTATION

Reductio ad Absurdum

A method of PROOF which proceeds by stating a proposition and then showing that it results in a contradiction, thus demonstrating the proposition to

be false. In the words of G. H. Hardy , "*Reductio ad absurdum*, which Euclid loved so much, is one of a mathematician's finest weapons. It is a far finer gambit than any CHESS gambit: a CHESS player may offer the sacrifice of a pawn or even a piece, but a mathematician offers the game" (Coxeter and Greitzer 1967, p. 16; Hardy 1993, p. 34).

Refinement

A refinement X of a COVER Y is a COVER such that every element $x \in X$ is a SUBSET of an element $y \in Y$.

See also Cover

Reflection

The operation of exchanging all points of a mathematical object with their mirror images (i.e., reflections in a mirror). Objects which do not change handedness under reflection are said to be amphichiral; those that do are said to be chiral.

If the plane of reflection is taken as the yz-plane, the reflection in 2- or 3-D space consists of making the transformation $x \to -x$ for each point. Consider an arbitrary point x_0 and a plane specified by the equation

$$ax + by + cz + d = 0. \tag{1}$$

This plane has normal vector

$$\mathbf{n} = \begin{bmatrix} a \\ b \\ c \end{bmatrix}, \tag{2}$$

and the point-plane distance is

$$D = \frac{|ax_0 + by_0 + cz_0 + d|}{\sqrt{a^2 + b^2 + c^2}}. \tag{3}$$

The position of the point reflected in the given plane is therefore given by

$$\mathbf{x}_0' = \mathbf{x}_0 - 2D\hat{\mathbf{n}}$$

$$= \begin{bmatrix} x_0 \\ y_0 \\ z_0 \end{bmatrix} - \frac{2|ax_0 + by_0 + cz_0 + d|}{a^2 + b^2 + c^2} \begin{bmatrix} a \\ b \\ c \end{bmatrix}. \tag{4}$$

Reflection Formula

Reflection Relation

Reflection Property

In the plane, the reflection property can be stated as three theorems (Ogilvy 1990, pp. 73–77):

1. The locus of the center of a variable circle, tangent to a fixed circle and passing through a fixed point inside that circle, is an ellipse.
2. If a variable circle is tangent to a fixed circle and also passes through a fixed point outside the circle, then the locus of its moving center is a hyperbola.
3. If a variable circle is tangent to a fixed straight line and also passes through a fixed point not on the line, then the locus of its moving center is a parabola.

Let $\alpha: I \to \mathbb{R}^2$ be a smooth regular parameterized curve in $\mathbb{R}^2$ defined on an open interval I, and let F_1 and F_2 be points in $\mathbb{P}^2 \backslash \alpha(I)$, where $\mathbb{P}^n$ is an n-D projective space. Then α has a reflection property with foci F_1 and F_2 if, for each point $P \in \alpha(I)$,

1. Any vector normal to the curve α at P lies in the span of the vectors $\overrightarrow{F_1P}$ and $\overrightarrow{F_2P}$.
2. The line normal to α at P bisects one of the pairs of opposite angles formed by the intersection of the lines joining F_1 and F_2 to P.

A smooth connected plane curve has a reflection property iff it is part of an ellipse, hyperbola, parabola, circle, or straight line.

Foci	Sign	Both foci finite	One focus finite	Both foci infinite
distinct	positive	confocal ellipses	confocal parabolas	parallel lines
distinct	negative	confocal hyperbola and perpendicular	confocal parabolas	parallel lines
		bisector of interfoci line segment		
equal		concentric circles		parallel lines

Let $S \in \mathbb{R}^3$ be a smooth connected surface, and let F_1 and F_2 be points in $\mathbb{P}^3 \backslash S$, where $\mathbb{P}^n$ is an n-D projective space. Then S has a reflection property with foci F_1 and F_2 if, for each point $P \in S$,

1. Any vector normal to S at P lies in the span of the vectors $\overrightarrow{F_1P}$ and $\overrightarrow{F_2P}$.
2. The line normal to S at P bisects one of the pairs of opposite angles formed by the intersection of the lines joining F_1 and F_2 to P.

A smooth connected surface has a reflection property iff it is part of an ellipsoid of revolution,

a HYPERBOLOID of revolution, a PARABOLOID of revolution, a SPHERE, or a PLANE.

Foci	Sign	Both foci finite	One focus finite	Both foci infinite
distinct	POSITIVE	confocal ellipsoids	confocal paraboloids	parallel planes
distinct	NEGATIVE	confocal hyperboloids and plane perpendicular bisector of inter-foci line segment	confocal paraboloids	parallel planes
equal		concentric spheres		parallel planes

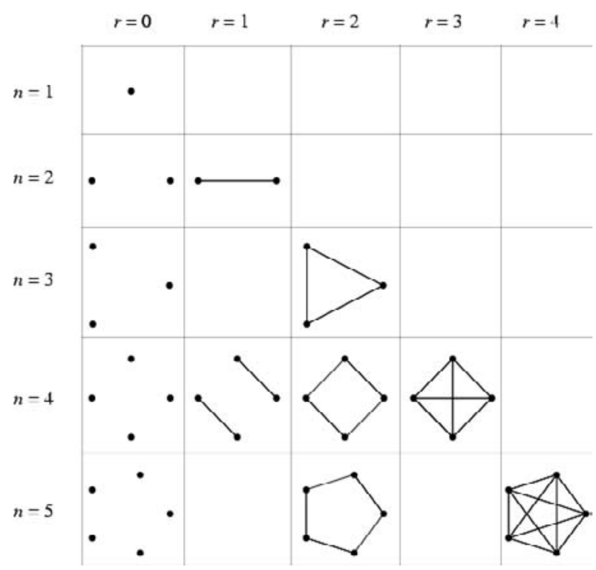
Regula Falsi

FALSE POSITION METHOD

Regular Function

ANALYTIC FUNCTION, HOLOMORPHIC FUNCTION, REGULAR RATIONAL FUNCTION

Regular Graph



A GRAPH is said to be regular of degree r if all LOCAL DEGREES are the same number r. A 0-regular graph is an EMPTY GRAPH, a 1-regular graph consists of disconnected edges, and a 2-regular graph consists of disconnected cycles. The first interesting case is therefore 3-regular graphs, which are called CUBIC GRAPHS (Harary 1994, pp. 14–15). Similarly, 4- and 5-regular graphs are called QUARTIC and QUINTIC GRAPHS, respectively.

For an r-regular graph on n nodes.

$$E = \tfrac{1}{2} nr,$$

where E is the number of EDGES. n-UNITRANSITIVE GRAPHS are sometimes called n-regular (Harary 1994, p. 174).

Let $N(n, r)$ be the number of r-regular graphs with n points. Then $0 \le r \le n-1$, $N(n, r) = N(n, n-1, -r)$, and $N(n,r) = 0$ when both n and r are ODD. Zhang and Yang give $N(p, r)$ for $p \le 12$. The numbers of nonisomorphic regular graphs with n nodes are 1, 2, 2, 4, 3, 8, 6, 22, 26, 176, ... (Sloane's A005176; Steinbach 1990). The numbers of nonisomorphic CONNECTED regular graphs of order $n = 1, 2, ...$ are 1, 1, 1, 2, 2, 5, 4, 17, 22, 167, ... (Sloane's A005177; Steinbach 1990)

The following table gives the numbers $N(n, r)$ of r-regular graphs for small numbers of nodes n (Sloane's A051031).

n	$N(n, 0)$	$N(n, 1)$	$N(n, 2)$	$N(n, 3)$	$N(n, 4)$	$N(n, 5)$	$N(n, 6)$
1	1						
2	1	1					
3	1	0	1				
4	1	1	1	1			
5	1	0	1	0	1		
6	1	1	2	2	1	1	
7	1	0	2	0	2	0	1

The following table gives the number of connected regular graphs of degree r on $n = r+1, r+2, ...$ nodes

for n even, and $n = r+1$, $r+3$, $r+5$, ... nodes for n odd.

r	Sloane	Numbers
4	A006820	1, 1, 2, 6, 16, 59, 265, 1544, ...
5	A006821	1, 3, 60, 7848, 3459383, ...
6	A006822	1, 1, 4, 21, 266, 7849, 367860, ...
7	A014377	1, 5, 1547, ...
8	A014378	1, 1, 6, 94, 10786, 3459386, ...
9	A014381	1, 9, 88193, ...
10	A014382	1, 1, 10, 540, 805579, ...
11	A014384	1, 13, 8037796, ...

Eisenbud, D. *Commutative Algebra with a View Toward Algebraic Geometry.* New York: Springer-Verlag, p. 242, 1995.

Regular Matrix

NONSINGULAR MATRIX

Regular Number

A number which has a finite DECIMAL expansion. A number such as $1/3 = 0.33333\ldots$ which is not regular is said to be nonregular.

See also DECIMAL EXPANSION, REPEATING DECIMAL

Regular Parameterization

A parameterization of a SURFACE $\mathbf{x}(u, v)$ in u and v is regular if the TANGENT VECTORS

$$\frac{\partial \mathbf{x}}{\partial u} \quad \text{and} \quad \frac{\partial \mathbf{x}}{\partial v}$$

are always LINEARLY INDEPENDENT.

Regular Patch

A regular patch is a PATCH $\mathbf{x} : U \to \mathbb{R}^n$ for which the JACOBIAN $J(\mathbf{x})(u, v)$ has rank 2 for all $(u, v) \in U$. A PATCH is said to be regular at a point $(u_0, v_0) \in U$ provided that its JACOBIAN has rank 2 at (u_0, v_0). For example, the points at $\phi = \pm\pi/2$ in the standard parameterization of the SPHERE $(\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi)$ are not regular.

An example of a PATCH which is regular but not INJECTIVE is the CYLINDER defined parametrically by $(\cos u,\ \sin u,\ v)$ with $u \in (-\infty,\ \infty)$ and $v \in (-2,\ 2)$. However, if $\mathbf{x} : U \to \mathbb{R}^n$ is an injective regular patch, then $\mathbf{x}$ maps U diffeomorphically onto $\mathbf{x}(U)$.

See also INJECTIVE PATCH, PATCH, REGULAR SURFACE

Regular Polychoron

There are sixteen regular polychora, six of which are convex (Wells 1986, p. 68) and ten of which are stellated (Wells 1991, p. 209). The regular convex polychora have four principal types of symmetry axes, and the projections into 3-spaces orthogonal to these may be called the "canonical" projections (R. Towle).

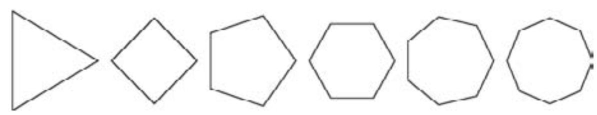
Of the six regular convex polychora, five are typically regarded as being analogous to the Platonic solids: the 4-simplex (a hyper-tetrahedron), the 4-cross polytope (a hyper-octahedron), the 4-cube (a hyper-cube), the 600-cell (a hyper-icosahedron), and the 120-cell (a hyper-dodecahedron). The 24-cell, however, has no perfect analogy in higher or lower spaces (R. Towle). The PENTATOPE and 24-CELL are self-dual, the 16-CELL is the dual of the TESSERACT, and the 600- and 120-CELLS are dual to each other.

The convex regular polychora are listed in the following table (Coxeter 1969, p. 414; Wells 1991, p. 210).

Name	Schläfli Symbol	Class	N_0	N_1	N_2	N_3
PENTATOPE	{3, 3, 3}	SIMPLEX	5	10	10	5
16-CELL	{3, 3, 4}	CROSS POLYTOPE	8	24	32	16
TESSERACT	{4, 3, 3}	HYPERCUBE	16	32	24	8
24-CELL	{3, 4, 3}		24	96	96	24
120-CELL	(5, 3, 3)		600	1200	720	120
600-CELL	{3, 3, 5}		120	720	1200	600

Here, N_0 is the number of VERTICES, N_1 the number of EDGES, N_2 the number of FACES, and N_3 the number of cells. These quantities satisfy the identity

$$N_0 - N_1 + N_2 - N_3 = 0,$$



which is a version of the POLYHEDRAL FORMULA.

Regular Polygon

An n-sided POLYGON in which the sides are all the same length and are symmetrically placed about a common center (i.e., the polygon is both EQUIANGULAR and EQUILATERAL). The sum of PERPENDICULARS from any point to the sides of a regular polygon of n sides is n times the APOTHEM. Only certain regular polygons are "CONSTRUCTIBLE" with RULER and STRAIGHTEDGE. The terms EQUILATERAL TRIANGLE and SQUARE refer to the regular 3- and 4-polygons, respectively. The words for POLYGONS with $n \geq 5$ sides (e.g., PENTAGON, HEXAGON, HEPTAGON, etc.) can refer to either regular or non-regular POLYGONS, although the terms generally refer to regular polygons in the absence of specific wording.

$n = 5$

Let s be the side length, r be the INRADIUS, and R the CIRCUMRADIUS of a regular polygon. Then

$$s = 2r \tan\left(\frac{\pi}{n}\right) \tag{1}$$

$$= 2R \sin\left(\frac{\pi}{n}\right) \tag{2}$$

$$r = \tfrac{1}{2} s \cot\left(\frac{\pi}{n}\right) \tag{3}$$

$$= R \cos\left(\frac{\pi}{n}\right) \tag{4}$$

$$R = \tfrac{1}{2} s \csc\left(\frac{\pi}{n}\right) \tag{5}$$

$$= r \sec\left(\frac{\pi}{n}\right) \tag{6}$$

$$A = \tfrac{1}{4} ns^2 \cot\left(\frac{\pi}{n}\right) \tag{7}$$

$$= nr^2 \tan\left(\frac{\pi}{n}\right) \tag{8}$$

$$= \tfrac{1}{2} nR^2 \sin\left(\frac{2\pi}{n}\right). \tag{9}$$

If the number of sides is doubled, then

$$s_{2n} = \sqrt{2R^2 - R\sqrt{4R^2 - s_n^2}} \tag{10}$$

$$A_{2n} = \frac{4rA_n}{2r + \sqrt{4r^2 + s_n^2}}. \tag{11}$$

Furthermore, if p_k and P_k are the PERIMETERS of the regular polygons inscribed in and circumscribed around a given CIRCLE and a_k and A_k their areas, then

$$P_{2n} = \frac{2p_n P_n}{p_n + P_n} \tag{12}$$

$$p_{2n} = \sqrt{p_n P_{2n}}, \tag{13}$$

and

$$a_{2n} = \sqrt{a_n A_n} \tag{14}$$

$$A_{2n} = \frac{2a_{2n}A_n}{a_{2n} + A_n} \tag{15}$$

(Beyer 1987, p. 125).

The following table gives parameters for the first few regular polygons, where α is the vertex angle, β is the central angle, r is the INRADIUS, R is the CIRCUMRADIUS, and A is the area (Williams 1979, p. 33).

$\{n\}$	α	β	r	R	A
$\{3\}$	$\frac{1}{3}\pi=60^\circ$	$\frac{2}{3}\pi=120^\circ$	$\frac{1}{6}\sqrt{3}$	$\frac{1}{3}\sqrt{3}$	$\frac{1}{4}\sqrt{3}$

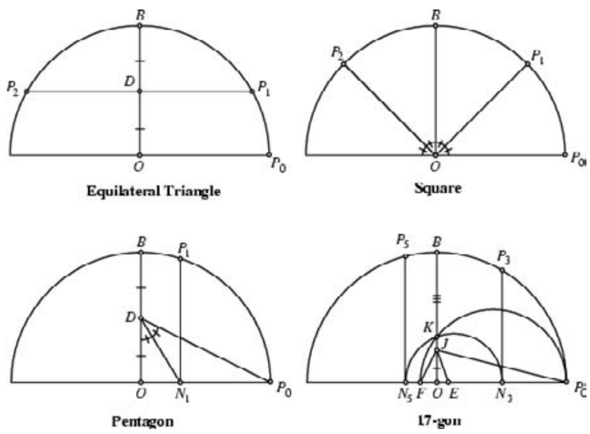
COMPASS and STRAIGHTEDGE constructions dating back to Euclid were capable of inscribing regular polygons of 3, 4, 5, 6, 8, 10, 12, 16, 20, 24, 32, 40, 48, 64, ..., sides. However, this listing is not a complete enumeration of "constructible" polygons. In fact, a regular n-gon is constructible only if $\phi(n)$ is a POWER of 2, where ϕ is the TOTIENT FUNCTION (this is a NECESSARY but not SUFFICIENT condition). More specifically, a regular n-gon ($n \geq 3$) can be constructed by STRAIGHTEDGE and COMPASS (i.e., can have trigonometric functions of its ANGLES expressed in terms of finite SQUARE ROOT extractions) IFF

$$n = 2^k p_1 p_2 \cdots p_s, \tag{16}$$

where k is in INTEGER ≥ 0 and the p_i are distinct FERMAT PRIMES. FERMAT NUMBERS are OF THE FORM

$$F_m = 2^{2^m} + 1, \tag{17}$$



where m is an INTEGER ≥ 0. The only known PRIMES of this form are 3, 5, 17, 257, and 65537.

The fact that this condition was SUFFICIENT was first proved by Gauss in 1796 when he was 19 years old, and it relies on the property of IRREDUCIBLE POLYNOMIALS that ROOTS composed of a finite number of SQUARE ROOT extractions exist only if the order of the equation is OF THE FORM 2^h. That this condition was also NECESSARY was not explicitly proven by Gauss, and the first proof of this fact is credited to Wantzel (1836).

Constructible values of n for $n < 300$ were given by Gauss (Smith 1994), and the first few are 2, 3, 4, 5, 6, 8, 10, 12, 15, 16, 17, 20, 24, 30, 32, 34, 40, 48, 51, 60, 64, 68, 80, 85, 96, 102, 120, 128, 136, 160, 170, 192, ... (Sloane's A003401). Gardner (1977) and independently Watkins (Conway and Guy 1996) noticed that the number of sides for constructible polygons with an ODD number of sides are given by the first 32 rows of PASCAL'S TRIANGLE (mod 2) interpreted as BINARY numbers, giving 1, 3, 5, 15, 17, 51, 85, 255, ... (Sloane's A004729, Conway and Guy 1996, p. 140).

1	1	1
1 1	1 1	3
1 2 1	1 0 1	5
1 3 3 1	1 1 1 1	15
1 4 6 4 1	1 0 0 0 1	17
1 5 10 10 5 1	1 1 0 0 1 1	51
1 6 15 20 15 6 1	1 0 1 0 1 0 1	85
1 7 21 35 35 21 7 1	1 1 1 1 1 1 1 1	255
1 8 28 56 70 56 28 8 1	1 0 0 0 0 0 0 0 1	257

Although constructions for the regular TRIANGLE, SQUARE, PENTAGON, and their derivatives had been given by Euclid, constructions based on the FERMAT PRIMES ≥ 17 were unknown to the ancients. The first explicit construction of a HEPTADECAGON (17-gon) was given by Erchinger in about 1800. Richelot and Schwendenwein found constructions for the 257-GON in 1832, and Hermes spent 10 years on the construction of the 65537-GON at Göttingen around 1900 (Coxeter 1969). Constructions for the EQUILATERAL TRIANGLE and SQUARE are trivial (top figures below). Elegant constructions for the PENTAGON and HEPTADECAGON are due to Richmond (1893) (bottom figures below).

Given a point, a CIRCLE may be constructed of any desired RADIUS, and a DIAMETER drawn through the center. Call the center O, and the right end of the DIAMETER P_0. The DIAMETER PERPENDICULAR to the original DIAMETER may be constructed by finding the PERPENDICULAR BISECTOR. Call the upper endpoint of this PERPENDICULAR DIAMETER B. For the PENTAGON, find the MIDPOINT of OB and call it D. Draw DP_0, and BISECT $\angle ODP_0$, calling the intersection point with OP_0 N_1. Draw N_1P_1 PARALLEL to OB, and the first two points of the PENTAGON are P_0 and P_1. The construction for the HEPTADECAGON is more complicated, but can be accomplished in 17 relatively simple steps. The construction problem has now been automated (Bishop 1978).

Regular Polyhedron

A polyhedron is said to be regular if its FACES and VERTEX FIGURES are REGULAR (not necessarily CONVEX) polygons (Coxeter 1973, p. 16). Using this definition, there are a total of nine regular polyhedra, five being the CONVEX PLATONIC SOLIDS and four being the CONCAVE (stellated) KEPLER-POINSOT SOLIDS. However, the term "regular polyhedra" is sometimes used to refer exclusively to the CONVEX PLATONIC SOLIDS.

It can be proven that only nine regular solids (in the Coxeter sense) exist by noting that a possible regular polyhedron must satisfy

$$\cos^2\left(\frac{\pi}{p}\right) + \cos^2\left(\frac{\pi}{q}\right) + \cos^2\left(\frac{\pi}{r}\right) = 1.$$

Gordon showed that the only solutions to

$$1 + \cos\phi_1 + \cos\phi_2 + \cos\phi_3 = 0$$

OF THE FORM $\phi_i = \pi m_i/n_i$ are the permutations of $(\frac{2}{3}\pi, \frac{2}{3}\pi, \frac{1}{3}\pi)$ and $(\frac{2}{3}\pi, \frac{2}{5}\pi, \frac{4}{5}\pi)$. This gives three permutations of (3, 3, 4) and six of (3, 5, $\frac{5}{3}$) as possible solutions to the first equation. Plugging back in gives the SCHLÄFLI SYMBOLS of possible regular polyhedra as {3, 3}, {3, 4}, {4, 3}, {3, 5}, {5, 3}, {3, $\frac{5}{2}$}, {$\frac{5}{2}$, 3}, {5, $\frac{5}{2}$}, and {$\frac{5}{2}$, 5} (Coxeter 1973, pp. 107–109). The first five of these are the PLATONIC SOLIDS and the remaining four the KEPLER-POINSOT SOLIDS.

Every regular polyhedron has $e+1$ axes of symmetry, where e is the number of EDGES, and $3h/2$ PLANES of symmetry, where h is the number of sides of the corresponding PETRIE POLYGON.

Regular Polytope

REGULAR POLYCHORON

Regular Prime

A PRIME which does not DIVIDE the CLASS NUMBER $h(p)$ of the CYCLOTOMIC FIELD obtained by adjoining a PRIMITIVE pTH ROOT OF UNITY to the FIELD of rationals. A PRIME p is regular IFF p does not divide the NUMERATORS of the BERNOULLI NUMBERS B_0, B_2, ..., B_{p-3}. A PRIME which is not regular is said to be an IRREGULAR PRIME.

In 1915, Jensen proved that there are infinitely many IRREGULAR PRIMES. It has not yet been proven that there are an INFINITE number of regular primes (Guy 1994, p. 145). Of the 283,145 PRIMES $< 4 \times 10^6$, 171,548 (or 60.59%) are regular (the conjectured FRACTION is $e^{-1/2} \approx 60.65\%$). The first few are 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 43, 47, ... (Sloane's A007703).

Regular Singular Point

Consider a second-order ORDINARY DIFFERENTIAL EQUATION

$$y''P(x)y' + Q(x)y = 0.$$

If $P(x)$ and $Q(x)$ remain FINITE at $x = x_0$, then x_0 is called an ORDINARY POINT. If either $P(x)$ or $Q(x)$ diverges as $x \to x_0$, then x_0 is called a singular point. If either $P(x)$ or $Q(x)$ diverges as $x \to x_0$ but $(x-x_0)P(x)$ and $(x-x_0)^2Q(x)$ remain FINITE as $x \to x_0$, then $x = x_0$ is called a regular singular point (or NONESSENTIAL SINGULARITY).

Regular Singularity

REGULAR SINGULAR POINT

Regular Skew Polyhedron

A regular skew polyhedron is a polyhedron whose faces and VERTEX FIGURES are regular SKEW POLYGONS. There are only three regular skew polyhedra in Euclidean 3-space (Coxeter 1937, Garner 1967), the simplest of which is $\{4, 6|4\}$.

Garner (1967) considered regular skew polyhedra in hyperbolic space $\mathbb{H}^3$, and shows that there are exactly 32 which are derived from honeycombs whose cells and vertex figures are derived from honeycombs whose cells and vertex figures are not inscribed in equidistant surfaces.

Regular Surface

A SUBSET $M \subset \mathbb{R}^n$ is called a regular surface if for each point $p \in M$, there exists a NEIGHBORHOOD V of p in $\mathbb{R}^n$ and a MAP $x: U \to \mathbb{R}^n$ of an OPEN SET $U \subset \mathbb{R}^2$ onto $V \cap M$ such that

1. x is differentiable,
2. $x: U \to V \cap M$ is a HOMEOMORPHISM, and
3. Each map $x: U \to M$ is a REGULAR PATCH.

Any open subset of a regular surface is also a regular surface.

See also REGULAR PATCH

Regularized Beta Function

The regularized beta function is defined by

$$I(z; a, b) = \frac{B(z; a, b)}{B(a, b)},$$

where $B(z; a, b)$ is the incomplete BETA FUNCTION and $B(a, b)$ is the complete BETA FUNCTION. The regularized beta function is sometimes also denoted $I_z(a, b)$ and is implemented in *Mathematica* as `BetaRegularized[z, a, b]`. The four-argument version `BetaRegularized[z1, z2, a, b]` is equivalent to $I(z_2; a, b) - I(z_1; a, b)$.

See also BETA FUNCTION, REGULARIZED GAMMA FUNCTION

Regularized Gamma Function

The regularized gamma functions are defined by

$$P(a, z) = 1 - Q(a, z) \equiv \frac{\gamma(a, z)}{\Gamma(a)} \tag{1}$$

and

$$Q(a, z) = 1 - P(a, z) \equiv \frac{\Gamma(a, z)}{\Gamma(a)},$$

where $\gamma(a, z)$ and $\Gamma(a, z)$ are INCOMPLETE GAMMA

FUNCTIONS and $\Gamma(a)$ is a complete GAMMA FUNCTION. The function $Q(a, z)$ is implemented in *Mathematica* as `GammaRegularized[a, z]`.

The derivatives of $P(a, z)$ and $Q(a, z)$ are

$$\frac{d}{dz} P(a, z) = \frac{e^{-z} z^{a-1}}{\Gamma(a)} \tag{2}$$

$$\frac{d}{dz} Q(a, z) = \frac{e^{-z} z^{a-1}}{\Gamma(a)}, \tag{3}$$

and the second derivatives are

$$\frac{d^2}{dz^2} P(a, z) = \frac{e^{-z}(a - z - 1) z^{a-2}}{\Gamma(a)} \tag{4}$$

$$\frac{d^2}{dz^2} Q(a, z) = \frac{e^{-z}(1 + z - a) z^{a-2}}{\Gamma(a)} \tag{5}$$

The integrals are

$$\int P(a, z)\, dz = \frac{z\Gamma(a) - z\Gamma(a, z) + \Gamma(a+1, z)}{\Gamma(a)} \tag{6}$$

$$\int Q(a, z)\, dz = \frac{z\Gamma(a, z) - \Gamma(a+1, z)}{\Gamma(a)} \tag{7}$$

Regulus

The locus of lines meeting three given SKEW LINES. ("Regulus" is also the name of the brightest star in the constellation Leo.)

Reidemeister Moves

In the 1930s, Reidemeister first rigorously proved that KNOTS exist which are distinct from the UNKNOT. He did this by showing that all KNOT deformations can be reduced to a sequence of three types of "moves," called the (I) TWIST MOVE, (II) POKE MOVE, and (III) SLIDE MOVE. These moves are most commonly called Reidemeister moves, although the term "equivalence moves" is sometimes also used (Aneziris 1999, p. 29).

REIDEMEISTER'S THEOREM guarantees that moves I, II, and III correspond to AMBIENT ISOTOPY (moves II and III alone correspond to REGULAR ISOTOPY). He then defined the concept of COLORABILITY, which is invariant under Reidemeister moves.

See also AMBIENT ISOTOPY, COLORABLE, KNOT MOVE, MARKOV MOVES, REGULAR ISOTOPY, UNKNOT

Relation

A relation is any SUBSET of a CARTESIAN PRODUCT. For instance, a SUBSET of $A \times B$, called a "BINARY RELATION from A to B," is a collection of ORDERED PAIRS (a, b) with first components from A and second components from B, and, in particular, a SUBSET of $A \times A$ is called a "relation on A." For a BINARY RELATION R, one often writes aRb to mean that (a, b) is in R.

Relational System

This entry contributed by VIKTOR BENGTSSON

A relational system is a structure $\mathcal{R} = (S, \{P_i : i \in I\}, \{f_j : j \in J\})$ consisting of a set S, a collection of relations $P_i (i \in I)$ on S, and a collection of functions $f_j (j \in J)$ on S.

Relative Cumulative Frequency

The CUMULATIVE FREQUENCY in a FREQUENCY DISTRIBUTION divided by the total number of data points.

Relative Degree

DEGREE (EXTENSION FIELD

Relative Entropy

Let a DISCRETE DISTRIBUTION have probability function p_k, and let a second DISCRETE DISTRIBUTION have probability function q_k. Then the relative entropy of p with respect to q, also called the Kullback-Leibler distance, is defined by

$$d = \sum_k p_k \ln\left(\frac{p_k}{q_k}\right).$$

Although relative entropy does not satisfy the triangle inequality and is therefore not a true metric, it satisfies many important mathematical properties. For example, it is a convex function of p_k, is always nonnegative, and equals zero only if $p_k = q_k$.

Relative entropy is a very important concept in quantum information theory, as well as statistical mechanics (Qian 2000).

Relative Error

Let the true value of a quantity be x and the measured or inferred value x_0. Then the relative error is defined by

$$\delta x = \frac{\Delta x}{x} = \frac{x_0 - x}{x} = \frac{x_0}{x} - 1,$$

where Δx is the ABSOLUTE ERROR. The relative error of the QUOTIENT or PRODUCT of a number of quantities is less than or equal to the SUM of their relative errors. The PERCENTAGE ERROR is 100% times the relative error.

Relative Maximum

A MAXIMUM within some NEIGHBORHOOD which need not be a GLOBAL MAXIMUM.

See also GLOBAL MAXIMUM, MAXIMUM, RELATIVE MINIMUM

Relative Minimum

A MINIMUM within some NEIGHBORHOOD which need not be a GLOBAL MINIMUM.

See also GLOBAL MINIMUM, MINIMUM, RELATIVE MAXIMUM

Relative Topology

If $A \subset B$ and B has a topology of open sets U_α then the relative topology on A is given by the collection of open sets $U_\alpha \cap A$.

Relatively Prime

Two integers are relatively prime if they share no common positive factors (divisors) except 1. Using the notation (m, n) to denote the GREATEST COMMON DIVISOR, two integers m and n are relatively prime if $(m, n) = 1$. Relatively prime integers are sometimes also called STRANGERS or COPRIME and are denoted $m \perp n$.

The probability that two INTEGERS picked at random are relatively prime is $[\zeta(2)]^{-1} = 6/\pi^2$, where $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Wells 1986, p. 28). This result is related to the fact that the GREATEST COMMON DIVISOR of m and n, $(m, n) = k$, can be interpreted as the number of LATTICE POINTS in the PLANE which lie on the straight LINE connecting the VECTORS $(0, 0)$ and (m, n) (excluding (m, n) itself). In fact, $6/\pi^2$ is the fractional number of LATTICE POINTS VISIBLE from the ORIGIN (Castellanos 1988, pp. 155–156).

Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)]^{-1} \approx 1.20206^{-1} \approx 0.831907, \quad (1)$$

where $\zeta(3)$ is APÉRY'S CONSTANT (Wells 1986, p. 29). This generalizes to k random integers (Schoenfeld 1976).

Remainder

In general, a remainder is a quantity "left over" after performing a particular algorithm. The term is most commonly used to refer to the number left over when two integers are divided by each other in INTEGER DIVISION. For example, $55\backslash 7 = 7$, with a remainder of 6. Of course in real division, there is no such thing as a remainder since, for example, $55/7 = 7 + 6/7$.

The term remainder is also sometimes applied to the RESIDUE of a CONGRUENCE.

Remainder Theorem

POLYNOMIAL REMAINDER THEOREM

Rembs' Surface

A surface of constant GAUSSIAN CURVATURE that can be given parametrically by

$$x = a(U \cos u - U' \sin u) \quad (1)$$

$$y = -a(U \sin u - U' \cos u) \quad (2)$$

$$z = v - aV', \quad (3)$$

where

$$U \equiv \frac{\cosh\left(u\sqrt{C}\right)}{\sqrt{C}} \quad (4)$$

$$V \equiv \frac{\cos\left(v\sqrt{C+1}\right)}{\sqrt{C+1}} \quad (5)$$

$$a \equiv \frac{2V}{(C+1)(U^2 - V^2)}, \quad (6)$$

and $U' = dU/du$, and $V' = dV/dv$. The value of v is restricted to

$$|v| \leq v_0 \equiv \frac{\pi}{2\sqrt{C+1}} \quad (7)$$

(Reckziegel 1986), and the values $v = \pm v_0$ correspond to the ends of the cleft in the surface. The surface illustrated above corresponds to $C = 1$.

Rembs' surface has FIRST FUNDAMENTAL FORM coefficients

$$E = \frac{16C(1+C)\cos^2\left(v\sqrt{C+1}\right)\cosh^2\left(u\sqrt{C}\right)}{\left[1 - C\cos\left(2v\sqrt{C+1}\right) + (C+1)\cosh\left(2u\sqrt{C}\right)\right]^2} \quad (8)$$

$$F = 0 \quad (9)$$

$$G = \frac{\left[1 + 2C + C\cos\left(2v\sqrt{C+1}\right) + (C+1)\cosh\left(2u\sqrt{C}\right)\right]^2}{\left[1 - C\cos\left(2v\sqrt{C+1}\right) + (C+1)\cosh\left(2u\sqrt{C}\right)\right]^2}, \quad (10)$$

SECOND FUNDAMENTAL FORM coefficients by similar, rather complicated expressions. The GAUSSIAN CURVATURE is

$$K = 1, \quad (11)$$

with the MEAN CURVATURE given by a rather complicated expression.

Remes Algorithm

REMEZ ALGORITHM

Remez Algorithm

Portions of this entry contributed by CHARLES BOND

Portions of this entry contributed by RONALD M. AARTS

An algorithm for determining optimal coefficients for digital FILTERS. The Remez algorithm in effect goes a step beyond the MINIMAX APPROXIMATION algorithm to give a slightly finer solution to an approximation problem.

The Remez exchange algorithm (Remez 1957) was first studied by Parks and McClellan (1972). The algorithm is an iterative procedure consisting of two steps. One step is the determination of candidate FILTER coefficients $h(n)$ from candidate "alternation frequencies," which involves solving a set of linear equations. The other step is the determination of candidate alternation frequencies from the candidate FILTER coefficients (Lim and Oppenheim 1988). Experience has shown that the algorithm converges very fast, and is widely used in practice to design optimal FILTERS.

A *FORTRAN* implementation is given by Rabiner (1975). A description emphasizing the mathematical foundations rather than digital signal processing applications is given by Cheney (1999), who also spells Remez as Remes (Cheney 1966, p. 96).

Removable Crossing

REDUCIBLE CROSSING

Removable Singularity

A SINGULAR POINT z_0 of a FUNCTION $f(z)$ for which it is possible to assign a COMPLEX NUMBER in such a way that $f(z)$ becomes ANALYTIC. A more precise way of defining a removable singularity is as a singularity z_0 of a function $f(z)$ about which the function $f(z)$ is bounded. For example, the point $x_0 = 0$ is a removable singularity in the SINC FUNCTION $\operatorname{sinc} x = \sin x/x$, since this function satisfies $\operatorname{sinc} 0 = 1$.

Rencontres Number

DERANGEMENT, SUBFACTORIAL

Rendezvous Values

MAGIC GEOMETRIC CONSTANTS

Rényi's Parking Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Given the CLOSED INTERVAL $[0,\ x]$ with $x > 1$, let 1-D "cars" of unit length be parked randomly on the interval. The MEAN number $M(x)$ of cars which can fit (without overlapping!) satisfies

$$M(x) = \begin{cases} 0 & \text{for } 0 \le x < 1 \\ 1 + \dfrac{2}{x-1}\displaystyle\int_0^{x-1} M(y)\,dy & \text{for } x \ge 1. \end{cases} \quad (1)$$

The mean density of the cars for large x is

$$m \equiv \lim_{x\to\infty} \frac{M(x)}{x} = \int_0^\infty \exp\left(-2\int_0^x \frac{1-e^{-v}}{y}\right)dx$$

$$= 0.7475979202\ldots \quad (2)$$

(Sloane's A050996). While the inner integral can be done analytically,

$$f(x) = \gamma + \Gamma(0,\ x) + \ln x, \quad (3)$$

where γ is the EULER-MASCHERONI CONSTANT and $\Gamma(0,\ x)$ is the incomplete GAMMA FUNCTION, it is not known how to do the outer one

$$m = \int_0^\infty \exp[-2\,f(x)]\,dx \quad (4)$$

$$= e^{-2\gamma}\int_0^\infty \frac{e^{-2\Gamma(0,\ x)}}{x^2} \quad (5)$$

$$= 2^{-2\gamma}\int_0^\infty \frac{e^{-2\mathrm{ei}(-x)}}{x^2}, \quad (6)$$

where $\mathrm{ei}(x)$ is the EXPONENTIAL INTEGRAL. The slowly converging series expansion for the integrand is given by

$$\frac{e^{-2\mathrm{ei}(-x)}}{x^2} = 1 - 2x + \tfrac{5}{2}x^2 - \tfrac{22}{9}x^3 + \tfrac{293}{144}x^4 - \tfrac{2711}{1800}x^5 + \ldots \quad (7)$$

(Sloane's A050994 and A050995).

In addition,

$$M(x) = mx + m - 1 + \mathcal{O}(x^{-n}) \quad (8)$$

for all n (Rényi 1958), which was strengthened by Dvoretzky and Robbins (1964) to

$$M(x) = mx + m - 1 + \mathcal{O}\left[\left(\frac{2e}{x}\right)^{x-3/2}\right] \quad (9)$$

Dvoretzky and Robbins (1964) also proved that

$$\inf_{x\le t\le x+1} \frac{M(t)+1}{t+1} \le m \le \sup_{x\le t\le x+1} \frac{M(t)+1}{t+1}. \quad (10)$$

Let $V(x)$ be the variance of the number of cars, then Dvoretzky and Robbins (1964) and Mannion (1964) showed that

$$v \equiv \lim_{z\to\infty} \frac{V(x)}{x}$$

$$= 2\int_0^\infty \left\{x\int_0^1 e^{-xy}R_2(y)\,dy + x^2\left[\int_0^\infty e^{-xy}R_1(y)\,dy\right]^2\right\}$$

$$\times\exp\left(-2\int_0^x \frac{1-e^{-y}}{y}\,dy\right)dx = 0.038156\ldots, \quad (11)$$

where

$$R_1(x) = M(x) - mx - m + 1 \quad (12)$$

$$R_2(x) = \begin{cases} (1-m-mx)^2 \\ \quad \text{for } 0 \le x \le 1 \\ 4(1-m)^2 \\ \quad \text{for } x = 1 \\ \dfrac{2}{x-1}\left[\displaystyle\int_0^{x-1} R_2(y)\,dy + \int_0^{x-1} R_1(y)R_1(x-y-1)\,dy\right] \\ \quad \text{for } x > 1 \end{cases} \quad (13)$$

and the numerical value is due to Blaisdell and Solomon (1970). Dvoretzky and Robbins (1964) also proved that

$$\inf_{x\le t\le x+1} \frac{V(t)}{t+1} \le v \le \sup_{x\le t\le x+1} \frac{V(t)}{t+1}, \quad (14)$$

and that

$$V(x) = vx + v + \mathcal{O}\left[\left(\frac{4e}{x}\right)^{x-4}\right]. \quad (15)$$

Palasti (1960) conjectured that in 2-D,

$$\lim_{x,\ y\to\infty} \frac{M(x,\ y)}{xy} = m^2, \quad (16)$$

but this has not yet been proven or disproven (Finch).

Repartition

Adéle

Repdigit

A number composed of a single digit is called a repdigit. If the digits are all 1s, the repdigit is called a repunit. The beast number 666 is a repdigit.

See also Keith Number, Repunit

Repeated Integral

A repeated integral is an integral taken multiple times over a single variable (as distinguished from a multiple integral, which consists of a number of integrals taken with respect to *different* variables). The first fundamental theorem of calculus states that if $F(x) = D^{-1} f(x)$ is the integral of $f(x)$, then

$$\int_0^x f(t)\,dt = F(x) - F(0). \tag{1}$$

Now, if $F(0) = 0$, then

$$F(x) = \int f(x)\,dx = \int_0^x f(t)\,dt.$$

It follows by induction that if $F(0) = F(F(0)) = \ldots = 0$, then the n-fold integral of $f(x)$ is given by

$$D^{-n} f(x) = \underbrace{\int \cdots \int_0^x}_{n} f(x)\,dx = \int_0^x \frac{f(t)(x-t)^{n-1}}{(n-1)!}\,dt. \tag{2}$$

Similarly, if $F(x_0) = F(F(x_0)) = \ldots = 0$, then

$$\underbrace{\int \cdots \int_{x_0}^x}_{n} f(x)\,dx = \int_{x_0}^x \frac{f(t)(x-t)^{n-1}}{(n-1)!}\,dt. \tag{3}$$

See also Fractional Integral, Fubini Theorem, Integral, Multiple Integral

Repeating Decimal

A number whose decimal representation eventually becomes periodic (i.e., the same sequence of digits repeats indefinitely) is called a repeating decimal. Numbers such as 0.5 can be regarded as repeating decimals since $0.5 = 0.5000\ldots = 0.4999\ldots$. All rational numbers have repeating decimals, e.g., $1/11 = 0.\overline{09}$. However, transcendental numbers, such as $\pi = 3.141592\ldots$ do not.

If $1/m$ is a repeating decimal and $1/n$ is a terminating decimal, them $1/(mn)$ has a nonperiodic part whose length is that of $1/n$ and a repeating part whose length is that of $1/m$ (Wells 1986, p. 60).

Replicate

One out of a set of identical observations in a given experiment under identical conditions.

Replicating Symbol

Shah Function

Representation

A representation of a group G is a group action of G on a vector space V by invertible linear maps. For example, the group of two elements $\mathbb{Z}_2 = \{0, 1\}$ has a representation ϕ by $\phi(0)v = v$ and $\phi(1)v = -v$. A representation is a group homomorphism $\phi : G \to GL(V)$.

Most groups have many different representations, possibly on different vector spaces. For example, the symmetric group $S_3 = \{e, (12), (13), (23), (123), (132)\}$ has a representation on $\mathbb{R}$ by

$$\phi_1(\sigma)v = \operatorname{sgn}(\sigma)v, \tag{1}$$

where sgn(σ) is the SIGNATURE of the PERMUTATION σ. It also has a representation on $\mathbb{R}^3$ by

$$\phi_2(\sigma)(x_1,\ x_2,\ x_3) = \left(x_{\sigma(1)},\ x_{\sigma(2)},\ x_{\sigma(3)}\right). \tag{2}$$

A representation gives a matrix for each element, and so another representation of S_3 is given by the matrices

$$\begin{bmatrix}1 & 0\\0 & 1\end{bmatrix}, \begin{bmatrix}0 & 1\\1 & 0\end{bmatrix}, \begin{bmatrix}-1 & 0\\-1 & 1\end{bmatrix},$$
$$\begin{bmatrix}1 & -1\\0 & -1\end{bmatrix}, \begin{bmatrix}-1 & 1\\-1 & 0\end{bmatrix}, \begin{bmatrix}0 & -1\\1 & -1\end{bmatrix}. \tag{3}$$

Two representations are considered equivalent if they are conjugates. For example, CONJUGATING the above matrices by

$$\begin{bmatrix}1 & 19\\0 & 1\end{bmatrix}$$

gives the following equivalent representation of S_3,

$$\begin{bmatrix}1 & 0\\0 & 1\end{bmatrix}, \begin{bmatrix}-19 & -360\\1 & 19\end{bmatrix}, \begin{bmatrix}18 & 323\\-1 & -18\end{bmatrix}$$
$$\begin{bmatrix}1 & 37\\0 & -1\end{bmatrix}, \begin{bmatrix}18 & 343\\-1 & -19\end{bmatrix}, \begin{bmatrix}-19 & -343\\1 & 18\end{bmatrix} \tag{4}$$

Any representation V of G can be RESTRICTED to a representation of any subgroup H, in which case, it is denoted Res_H^G. More surprisingly, any representation W on H can be extended to a representation of G, on a larger VECTOR SPACE V, called the INDUCED REPRESENTATION.

Representations have applications to many branches of mathematics, aside from applications to physics and chemistry. The name of the theory depends on the GROUP G and on the VECTOR SPACE V. Different approaches are required depending on whether G is a FINITE GROUP, an infinite DISCRETE GROUP, or a LIE GROUP. Another important ingredient is the field of scalars for V. The vector space V can be infinite dimensional such as a HILBERT SPACE. Also, special kinds of representations may require that a vector space structure is preserved. For instance, a UNITARY REPRESENTATION is a GROUP HOMOMORPHISM $\phi : G \to U(V)$ into the group of UNITARY TRANSFORMATIONS which preserve a HERMITIAN INNER PRODUCT on V.

In favorable situations, such as a finite group, an arbitrary representation will break up into IRREDUCIBLE REPRESENTATIONS, i.e., $V = \oplus V_i$ where the V_i are irreducible. For many groups, the irreducible representations have been classified.

Representation (Lie Algebra)

A representation of a LIE ALGEBRA $\mathfrak{g}$ is a LINEAR MAP

$$\psi : \mathfrak{g} \to M(V),$$

where $M(V)$ is the set of all linear transformations of a VECTOR SPACE V. In particular, if $V = \mathbb{R}^n$, then $M(V)$ is the set of $n \times n$ square matrices. The map ψ is required to be a map of LIE ALGEBRAS so that

$$\psi([A,\ B]) = \psi(A)\psi(B) - \psi(B)\psi(A)$$

for all $A,\ B \in \mathfrak{g}$. Note that the expression AB only makes sense as a MATRIX PRODUCT in a representation. For example, if A and B are SKEW SYMMETRIC MATRICES, then $AB - BA$ is skew-symmetric, but AB may not be skew symmetric.

The possible IRREDUCIBLE REPRESENTATIONS of complex Lie algebras are determined by the classification of the SEMISIMPLE LIE ALGEBRAS. Any IRREDUCIBLE REPRESENTATION V of a complex LIE ALGEBRA $\mathfrak{g}$ is the TENSOR PRODUCT $V = V_0 \otimes L$, where V_0 is an IRREDUCIBLE REPRESENTATION of the quotient $\mathfrak{g}_{ss}/\mathrm{Rad}(\mathfrak{g})$ of the algebra $\mathfrak{g}$ and its RADICAL, and L is a one-dimensional representation.

A LIE ALGEBRA may be associated with a LIE GROUP, in which case it reflects the local structure of the LIE GROUP. Whenever a LIE GROUP G has a REPRESENTATION on V, its TANGENT SPACE at the identity, which is a LIE ALGEBRA, has a LIE ALGEBRA representation on V given by the differential at the identity. Conversely, if a CONNECTED LIE GROUP G corresponds to the Lie algebra $\mathfrak{g}$, and $\mathfrak{g}$ has a LIE ALGEBRA representation on V, then G has a REPRESENTATION on V given by the MATRIX EXPONENTIAL.

Repunit

A (generalized) repunit to the base b is a number of the form

$$M_n^b = \frac{b^n - 1}{b - 1}.$$

The term "repunit" was coined by Beiler (1966), who also gave the first tabulation of known factors. Repunits $M_n = M_n^2 = 2^n - 1$ with $b = 2$ are called Mersenne numbers. If $b = 10$, the number is called a repunit (since the digits are all 1s). A number of the form

$$R_n = \frac{10^n - 1}{10 - 1} = R_n = \frac{10^n - 1}{9}$$

is therefore a (decimal) repunit of order n.

Williams and Seah (1979) factored generalized repunits for $3 \le b \le 12$ and $2 \le n \le 1000$. A (base-10) repunit can be prime only if n is prime, since otherwise $10^{ab} - 1$ is a binomial number which can be factored algebraically. In fact, if $n = 2a$ is even, then $10^{2a} - 1 = (10^a - 1)(10^a + 1)$.

The number of factors for the base-10 repunits for $n = 1, 2, \ldots$ are 1, 1, 2, 2, 2, 5, 2, 4, 4, 4, 2, 7, 3, ... (Sloane's A046053). The only known base-10 repunit primes R_n are for $n = 2$, 19, 23, 317, 1031, 49081, (Sloane's A004023; Madachy 1979, Williams and Dubner 1986, Ball and Coxeter 1987, Granlund, Dubner 1999). Williams and Dubner (1986) proved R_{1031} to be prime. T. Granlund completed a search up to 45,000 in 1998 using two months of CPU time on a parallel computer. The search was extended by H. Dubner in 1999, culminating in the discovery of the probable prime $R_{49,081}$.

Yates (1982) published all the repunit factors for $n \leq 1000$, a portion of which are reproduced in the *Mathematica* notebook by Weisstein. Brillhart *et al.* (1988) gave a table of repunit factors which cannot be obtained algebraically, and a continuously updated version of this table is now maintained on-line. These tables include factors for $10^n - 1$ (with $n \leq 209$ odd) and $10^n + 1$ (for $n \leq 210$ EVEN and ODD) in the files ftp://sable.ox.ac.uk/pub/math/cunningham/10- and ftp://sable.ox.ac.uk/pub/math/cunningham/10+.
After algebraically factoring R_n, these types of factors are sufficient for complete factorizations.

A SMITH NUMBER can be constructed from every factored repunit.

Residual

The residual is the sum of deviations from a best-fit curve of arbitrary form.

$$R \equiv \sum [y_i - f(x_i, a_1, \ldots, a_n)]^2.$$

The residual should not be confused with the CORRELATION COEFFICIENT.

Residual vs. Predictor Plot

A plot of y_i versus the ESTIMATOR $e_i \equiv \hat{y}_i - y_i$. Random scatter indicates the model is probably good. A pattern indicates a problem with the model. If the spread in e_i increases as y_i increases, the errors are called HETEROSCEDASTIC.

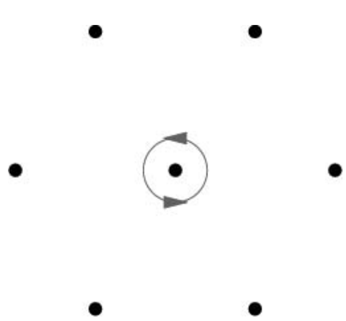
Residue



BIQUADRATIC RESIDUE, COMMON RESIDUE, COMPLETE RESIDUE SYSTEM, CUBIC RESIDUE, MINIMAL RESIDUE, QUADRATIC RESIDUE, RESIDUE CLASS, RESIDUE (COMPLEX ANALYSIS), RESIDUE (CONGRUENCE), RESIDUE INDEX, RESIDUE THEOREM

Residue (Complex Analysis)

The constant a_{-1} in the LAURENT SERIES

$$f(z) = \sum_{n=-\infty}^{\infty} a_n (z - z_0)^n \tag{1}$$

of $f(z)$ about a point z_0 is called the residue of $f(z)$. Unless z_0 is a POLE of f, its residue is zero. The residue of a function f at a point z_0 may be denoted $\text{Res}_{z=z}(f(z))$. Two basic examples of residues are given by $\text{Res}_{z=0}\, 1/z = 1$ and $\text{Res}_{z=0}\, 1/z^n = 0$ for $n > 1$. The residue is implemented in *Mathematica* as `Residue[`*f*`, {`*z*`, `*z0*`}]`.

The residue is also defined by

$$\int_\gamma f\, dz, \tag{2}$$

where γ is clockwise simple closed CONTOUR, small enough to avoid any other poles of f. In fact, any clockwise path with WINDING NUMBER 1 which does not contain any other poles gives the same result by the CAUCHY INTEGRAL FORMULA. The above diagram shows a suitable CONTOUR for which to define the residue of function, where the poles are indicated as black dots.

It is more natural to consider the residue of a MEROMORPHIC ONE-FORM because it is independent of the choice of coordinate. On a RIEMANN SURFACE, the residue is defined for a MEROMORPHIC ONE-FORM α at a point p by writing $\alpha = f\, dz$ in a coordinate z around p. Then

$$\operatorname*{Res}_p \alpha = \operatorname*{Res}_{z=p} f. \tag{3}$$

The sum of the residues of $\int f\, dz$ is zero on the RIEMANN SPHERE. More generally, the sum of the residues of a MEROMORPHIC ONE-FORM on a compact RIEMANN SURFACE must be zero.

The residues of a function $f(z)$ may be found without explicitly expanding into a LAURENT SERIES as follows. If $f(z)$ has a POLE of order m at z_0, then $a_n = 0$ for $n < -m$ and $a_{-m} \neq 0$. Therefore,

$$f(z) = \sum_{n=-m}^{\infty} a_n (z - z_0)^n = \sum_{n=0}^{\infty} a_{-m+n} (z - z_0)^{-m+n} \tag{4}$$

$$(z - z_0)^m f(z) = \sum_{n=0}^{\infty} a_{-m+n} (z - z_0)^n \tag{5}$$

$$\frac{d}{dz}[(z - z_0)^m f(z)] = \sum_{n=0}^{\infty} n a_{-m+n} (z - z_0)^{n-1}$$

$$= \sum_{n=1}^{\infty} n a_{-m+n} (z - z_0)^{n-1}$$

$$= \sum_{n=0}^{\infty} (n+1) a_{-m+n+1} (z - z_0)^n \tag{6}$$

$$\frac{d^2}{dz^2}[(z - z_0)^m f(z)] = \sum_{n=0}^{\infty} n(n+1) a_{-m+n+1} (z - z_0)^{n-1}$$

$$= \sum_{n=1}^{\infty} n(n+1) a_{-m+n+1} (z - z_0)^{n-1}$$

$$= \sum_{n=0}^{\infty} (n+1)(n+2) a_{-m+n+2} (z - z_0)^n. \tag{7}$$

Iterating,

$$\frac{d^{m-1}}{dz^{m-1}}[(z-z_0)^m f(z)]$$
$$=\sum_{n=0}^{\infty}(n+1)(n+2)(n+m-1)a_{n-1}(z-z_0)^n$$
$$=(m-1)!a_{-1}+\sum_{n=1}^{\infty}(n+1)(n+2)$$
$$\times(n+m-1)a_{n-1}(z-z_0)^{n-1}. \qquad (8)$$

So

$$\lim_{x\to z_0}\frac{d^{m-1}}{dz^{m-1}}[(z-z_0)^m f(z)]=\lim_{z\to z_0}(m-1)!a_{-1}+0$$
$$=(m-1)!a_{-1}, \qquad (9)$$

and the residue is

$$a_{-1}=\frac{1}{(m-1)!}\frac{d^{m-1}}{dz^{m-1}}[(z-z_0)^m f(z)]_{z=z_0}. \qquad (10)$$

The residues of a HOLOMORPHIC FUNCTION at its POLES characterize a great deal of the structure of a function, appearing for example in the amazing RESIDUE THEOREM of CONTOUR INTEGRATION.

Residue (Congruence)

The number b in the CONGRUENCE $a \equiv b \pmod{m}$ is called the residue of $a \pmod{m}$. The residue of large numbers can be computed quickly using CONGRUENCES. For example, to find $37^{13} \pmod{17}$, note that

$$37 \equiv 3$$
$$37^2 \equiv 3^2 \equiv 9 \equiv -8$$
$$37^4 \equiv 81 \equiv -4$$
$$37^8 \equiv 16 \equiv -1,$$

so

$$37^{13} \equiv 37^{1+4+8} \equiv 3(-4)(-1) \equiv 12 \pmod{17}.$$

See also COMMON RESIDUE, CONGRUENCE, MINIMAL RESIDUE

References

Shanks, D. *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, pp. 55–56, 1993.

Residue Class

The residue classes of a function $f(x)$ mod n are all possible values of the RESIDUE $f(x) \pmod{n}$. For example, the residue classes of $x^2 \pmod 6$ are $\{0, 1, 3, 4\}$, since

$$0^2 \equiv 0 \pmod 6$$
$$1^2 \equiv 1 \pmod 6$$
$$2^2 \equiv 4 \pmod 6$$
$$3^2 \equiv 3 \pmod 6$$
$$4^2 \equiv 4 \pmod 6$$
$$5^2 \equiv 1 \pmod 6$$

are all the possible residues. A COMPLETE RESIDUE SYSTEM is a set of integers containing one element from each class, so $\{0, 1, 9, 16\}$ would be a COMPLETE RESIDUE SYSTEM for $x^2 \pmod 6$, as would $\{0, 5, 3, 4\}$, etc.

The $\phi(m)$ residue classes prime to m form a GROUP under the binary multiplication operation (mod m), where $\phi(m)$ is the TOTIENT FUNCTION (Shanks 1993) and the GROUP is classed a MODULO MULTIPLICATION GROUP.

COMPLETE RESIDUE SYSTEM

Residue Theorem

Given an ANALYTIC FUNCTION $f(z)$ whose LAURENT SERIES is given by

$$f(z) = \sum_{n=-\infty}^{\infty} a_n (z - z_0)^n, \tag{1}$$

and integrate term by term using a closed CONTOUR γ encircling z_0,

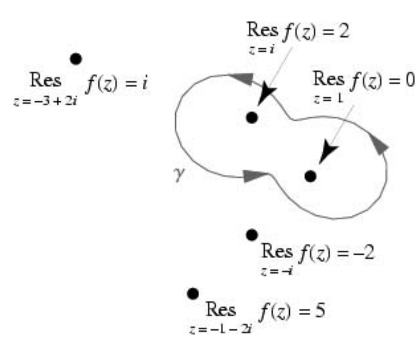
$$\begin{aligned}\int_\gamma f(z)\,dz &= \sum_{n=-\infty}^{\infty} a_n \int_\gamma (z - z_0)^n\,dz \\ &= \sum_{n=-\infty}^{-2} a_n \int_\gamma (z - z_0)^n\,dz + a_{-1} \int_\gamma \frac{dz}{z - z_0} \\ &\quad + \sum_{n=0}^{\infty} a_n \int_\gamma (z - z_0)^n\,dz. \end{aligned}\tag{2}$$

The CAUCHY INTEGRAL THEOREM requires that the first and last terms vanish, so we have

$$\int_\gamma f(x)\,dz = a_{-1} \int_\gamma \frac{dz}{z - z_0}, \tag{3}$$

where a_{-1} is the RESIDUE. Using the CONTOUR $z = \gamma(t) = e^{it} + z_0$ gives

$$\int_\gamma \frac{dz}{z - z_0} = \int_0^{2\pi} \frac{ie^{it}\,dt}{e^{it}} = 2\pi i, \tag{4}$$



so we have

$$\int_\gamma f(z)\,dz = 2\pi i a_{-1}. \tag{5}$$

If the contour γ encloses multiple poles, then the theorem gives the general result

$$\int_\gamma f(z)\,dz = 2\pi i \sum_{a \in A} \operatorname*{Res}_{z=a_i} f(z), \tag{6}$$

where A is the set of poles contained inside the contour. This amazing theorem therefore says that the value of a CONTOUR INTEGRAL for *any* contour in the COMPLEX PLANE depends *only* on the properties of a few very special points *inside* the contour.

The diagram above shows an example of the residue theorem applied to the illustrated CONTOUR γ and the function

$$g(z) = \frac{3}{(z-1)^2} + \frac{2}{z - i} - \frac{2}{z + i} + \frac{i}{z + 3 - 2i} + \frac{5}{z + 1 + 2i}. \tag{7}$$

Only the poles at 1 and i are contained in the contour, which have residues of 0 and 2, respectively. The values of the CONTOUR INTEGRAL is therefore given by

$$\int_\gamma g(z)\,dz = 2\pi i(0 + 2) = 4\pi i.$$

Resistor Network

Consider a network of n resistors R_i so that R_2 may be connected in series or parallel with R_1, R_3 may be connected in series or parallel with the network consisting of R_1 and R_2, and so on. The resistance of two resistors in series is given by

$$R_{\text{net, series}} = R_1 + R_2,$$

and of two resistors in parallel by

$$R_{\text{net, parallel}} = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2}}.$$

The possible values for two resistors with resistances a and b are therefore

$$a + b,\ \frac{1}{\frac{1}{a} + \frac{1}{b}},$$

for three resistances a, b, and c are

$$a + b + c,\ a + \frac{1}{\frac{1}{b} + \frac{1}{c}},\ b + \frac{1}{\frac{1}{a} + \frac{1}{c}},\ c + \frac{1}{\frac{1}{a} + \frac{1}{b}}$$

$$\frac{1}{\frac{1}{a}+\frac{1}{b+c}}, \frac{1}{\frac{1}{b}+\frac{1}{a+c}}, \frac{1}{\frac{1}{c}+\frac{1}{a+b}}, \frac{1}{\frac{1}{a}+\frac{1}{b}+\frac{1}{c}},$$

and so on. These are obviously all rational numbers, and the numbers of distinct arrangements for $n=1$, 2, ..., are 1, 2, 8, 46, 332, 2874, ... (Sloane's A005840), which also arises in a completely different context (Stanley 1991).

If the values are restricted to $a=b=\ldots=1$, then there are 2^{n-1} possible resistances for n 1-Ω resistors, ranging from a minimum of $1/n$ to a maximum of n. Amazingly, the largest denominators for $n=1$, 2, ... are 1, 2, 3, 5, 8, 13, 21, ..., which are immediately recognizable as the FIBONACCI NUMBERS (Sloane's A000045). The following table gives the values possible for small n.

n	Possible resistances
1	1
2	$\frac{1}{2}$, 2
3	$\frac{1}{3}$, $\frac{2}{3}$, $\frac{3}{2}$, 3
4	$\frac{1}{4}$, $\frac{2}{5}$, $\frac{3}{5}$, $\frac{3}{4}$, $\frac{4}{3}$, $\frac{5}{3}$, $\frac{5}{2}$, 4

If the n resistors are given the values 1, 2, ..., n, then the numbers of possible net resistances for 1, 2, ... resistors are 1, 2, 8, 44, 298, 2350, ... (Sloane's A051045). The following table gives the values possible for small n.

n	Possible resistances
1	1
2	$\frac{2}{3}$, 3

Resolution

Resolution is a widely used word with many different meanings. It can refer to resolution of equations, resolution of singularities (in ALGEBRAIC GEOMETRY), resolution of modules or more sophisticated structures, etc. In a BLOCK DESIGN, a PARTITION R of a BIBD's set of blocks B into PARALLEL CLASSES, each of which in turn partitions the set V, is called a resolution (Abel and Furino 1996).

A resolution of the MODULE M over the RING R is a complex of R-modules C_i and morphisms d_i and a MORPHISM ϵ such that

$$\cdots \to C_i \to^{d_i} C_{i-1} \to \cdots \to C_0 \to^{\epsilon} M \to 0$$

satisfying the following conditions:

1. The composition of any two consecutive morphisms is the zero map,
2. For all i, $(\ker d_i)/(\operatorname{im} d_{i+1})=0$,
3. $C_0/(\ker \epsilon)\simeq M$,

where ker is the kernel and im is the image. Here, the quotient

$$\frac{(\ker d_i)}{(\operatorname{im} d_{i+1})}$$

is the ith HOMOLOGY GROUP.

If all modules C_i are projective (free), then the resolution is called projective (free). There is a similar concept for resolutions "to the right" of M, which are called injective resolutions.

Resolution Class

PARALLEL CLASS

Resolution Modulus

The least POSITIVE INTEGER m^* with the property that $\chi(y)=1$ whenever $y\equiv 1 \pmod{m^*}$ and $(y, m)=1$.

Resolvable

A balanced incomplete BLOCK DESIGN (B, V) is called resolvable if there exists a PARTITION R of its set of blocks B into PARALLEL CLASSES, each of which in turn partitions the set V. The partition R is called a RESOLUTION.

See also BLOCK DESIGN, PARALLEL CLASS

Resolve

QUANTIFIER ELIMINATION

Resolving Tree

A tree of LINKS obtained by repeatedly choosing a crossing, applying the SKEIN RELATIONSHIP to obtain two simpler LINKS, and repeating the process. The DEPTH of a resolving tree is the number of levels of links, not including the top. The DEPTH of the LINK is the minimal depth for any resolving tree of that LINK.

Resonance Overlap

Isolated resonances in a DYNAMICAL SYSTEM can cause considerable distortion of preserved TORI in their NEIGHBORHOOD, but they do not introduce any CHAOS into a system. However, when two or more resonances are simultaneously present, they will render a system nonintegrable. Furthermore, if they are sufficiently "close" to each other, they will result in the appearance of widespread (large-scale) CHAOS.

To investigate this problem, Walker and Ford (1969) took the integrable Hamiltonian

$$H_0(I_1,\ I_2)=I_1+I_2-I_1^2-3I_1I_2+I_2^2$$

and investigated the effect of adding a 2:2 resonance and a 3:2 resonance

$$H(\mathbf{I},\ \theta)=H_0(\mathbf{I})+\alpha I_1I_2\cos(2\theta_1-2\theta_2)$$
$$+\beta I_1^{3/2}I_2\cos(2\theta_1-3\theta_2).$$

At low energies, the resonant zones are well-separated. As the energy increases, the zones overlap and a "macroscopic zone of instability" appears. When the overlap starts, many higher-order resonances are also involved so fairly large areas of PHASE SPACE have their TORI destroyed and the ensuing CHAOS is "widespread" since trajectories are now free to wander between regions that previously were separated by nonresonant TORI.

Walker and Ford (1969) were able to numerically predict the energy at which the overlap of the resonances first occurred. They plotted the θ_2-axis intercepts of the inner 2:2 and the outer 2:3 separatrices as a function of total energy. The energy at which they crossed was found to be identical to that at which 2:2 and 2:3 resonance zones began to overlap.

Restricted Divisor Function

The sum of the ALIQUOT DIVISORS of n, given by

$$s(n)\equiv\sigma(n)-n,$$

where $\sigma(n)$ is the DIVISOR FUNCTION. The first few values are 0, 1, 1, 3, 1, 6, 1, 7, 4, 8, 1, 16, ... (Sloane's A001065).

See also DIVISOR FUNCTION

Restricted Growth Function

RESTRICTED GROWTH STRING

Restricted Growth String

For a SET PARTITION of n elements, the n-character string $a_1 a_2 \dots a_n$ in which each character gives the BLOCK ($\mathbf{B}_0$, $\mathbf{B}_1$, ...) in which the corresponding element belongs is called the restricted growth string (or sometimes the RESTRICTED GROWTH FUNCTION). For example, for the SET PARTITION $\{\{1\}, \{2\}, \{3, 4\}\}$, the restricted growth string would be 0122. If the BLOCKS are "sorted" so that $a_1 = 0$, then the restricted growth string satisfies the INEQUALITY

$$a_{i+1} \leq 1 + \max\{a_1, a_2, \dots, a_i\}$$

for $i = 1, 2, ..., n-1$.

References

Ruskey, F. "Info About Set Partitions." http://www.theory.csc.uvic.ca/~cos/inf/setp/SetPartitions.html.

Restriction (Representation)

A REPRESENTATION of a GROUP G on a VECTOR SPACE V can be restricted to a SUBGROUP H. For example, the SYMMETRIC GROUP on three letters has a representation ϕ on $\mathbb{R}^2$ by

$$\phi(e) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{1}$$

$$\phi(12) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \tag{2}$$

$$\phi(13) = \begin{bmatrix} -1 & 0 \\ -1 & 1 \end{bmatrix} \tag{3}$$

$$\phi(23) = \begin{bmatrix} 1 & -1 \\ 0 & -1 \end{bmatrix} \tag{4}$$

$$\phi(123) = \begin{bmatrix} -1 & 1 \\ -1 & 0 \end{bmatrix} \tag{5}$$

$$\phi(132) = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix} \tag{6}$$

that can be restricted to the subgroup of ORDER 3,

$$\phi(e) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{7}$$

$$\phi(123) = \begin{bmatrix} -1 & 1 \\ -1 & 0 \end{bmatrix} \tag{8}$$

$$\phi(132) = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix} \tag{9}$$

See also FROBENIUS RECIPROCITY, REPRESENTATION, VECTOR SPACE

Resultant

Given a POLYNOMIAL $p(x)$ of degree n with roots α_i, $i = 1, ..., n$ and a POLYNOMIAL $q(x)$ of degree m with roots β_j, $j = 1, ..., m$, the resultant is defined by

$$\rho(p, q) = \prod_{i=1}^{n} \prod_{j=1}^{m} (\beta_j - \alpha_i).$$

The notation $R(p, q)$ is also used.

There exists an ALGORITHM similar to the EUCLIDEAN ALGORITHM for computing resultants (Pohst and Zassenhaus 1989). The resultant of two polynomials can be computed using the *Mathematica* command `Resultant`[*poly1*, *poly2*, *var*].

Resultants for a few simple pairs of polynomials include

$$\rho(x-a, x-b) = a-b$$

$$\rho((x-a)(x-b), x-c) = (a-c)(b-c)$$

$$\rho((x-a)(x-b), (x-c)(x-d)) = (a-c)(b-c)(a-d)(b-d).$$

The resultant is the DETERMINANT of the corresponding SYLVESTER MATRIX. Given p and q, then

$$h(x) = \rho(q(t), p(x-t))$$

is a POLYNOMIAL of degree mn, having as its roots all sums OF THE FORM $\alpha_i + \beta_j$.

Reuleaux Tetrahedron

The Reuleaux tetrahedron is the 3-dimensional solid common to four SPHERES of equal radius placed so that the center of each sphere lies on the surface of the other three. The centers of the spheres are therefore located at the vertices of a regular TETRAHEDRON, and the solid consists of an "inflated" tetrahedron with four curved edges.

To analyze the Reuleaux tetrahedron, fix a TETRAHEDRON of unit edge length with its vertices at $(0, 0, -\sqrt{6}/4)$, $(\sqrt{3}/3, 0, \sqrt{6}/12)$, $(-\sqrt{3}/6, 1/2, \sqrt{6}/12)$, and $(-\sqrt{3}/6, -1/2, \sqrt{6}/12)$. Simultaneously solving the equations of three of four spheres for x and y as a function of z then gives

$$x = \tfrac{1}{2}\sqrt{2}z + \tfrac{1}{4}\sqrt{\tfrac{15}{2} - 6z(\sqrt{6}+6z)} \qquad (1)$$

$$y = \frac{4\sqrt{3}z + \sqrt{5 - 4z(\sqrt{6}+6z)}}{4\sqrt{2}}. \qquad (2)$$

Half an arc is traced out as z passes from $\sqrt{6}/12$ to $(6-\sqrt{6})/12$, and

$$ds = \sqrt{\left(\frac{dx}{dz}\right)^2 + \left(\frac{dy}{dz}\right)^2 + 1}\, dz$$

$$= 3\sqrt{\frac{2}{5 - 4z(\sqrt{6}+6z)}}\, dz, \qquad (3)$$

so the ARC LENGTH of the curves connecting the vertices is given by

$$s = \int ds$$

$$= 6\sqrt{2}\int_{\sqrt{6}/12}^{(6-\sqrt{6})/12} \left[5 - 4z\left(\sqrt{6}+6z\right)\right]^{-1/2} dz. \qquad (4)$$

Making a change of coordinates,

$$s = \sqrt{3}\int_2^{\sqrt{6}} (6-u^2)^{-1/2}\, du = \sqrt{3}\cot^{-1}\left(\sqrt{2}\right) \qquad (5)$$

$$\approx 1.06604.$$

The VOLUME is significantly trickier to calculate analytically. Set up SPHERICAL COORDINATES from the *centroid* of the TETRAHEDRON, so that the distance from the bottom vertex to the radius vector is 1, i.e.,

$$r^2\cos^2\sin^2\phi + r^2\sin^2\theta\sin^2\phi + \left(r + \tfrac{1}{4}\sqrt{6}\right)^2 = 1, \quad (6)$$

giving

$$r(\theta, \phi) = \tfrac{1}{4}\left[\sqrt{3\cos(2\phi)+13} - \sqrt{6}\cos\phi\right]. \qquad (7)$$

By symmetry, the volume of the Reuleaux tetrahedron is given by

$$V = 24\int_0^{\pi/3}\int_0^{\phi(\theta)}\int_0^{r(\theta,\phi)} r^2\sin\phi\, dr\, d\phi\, d\theta. \qquad (8)$$

The integral over r can be done immediately,

$$V = \tfrac{1}{8}\int_0^{\pi/3}\int_0^{\phi(\theta)}\left[\sqrt{3\cos(2\phi)+13} - \sqrt{6}\cos\phi\right]^3 \sin\phi\, d\phi\, d\theta. \qquad (9)$$

Now parameterize the top right edge as a function of the azimuthal coordinate θ as

$$x = \frac{\cos\theta}{\sqrt{3}\cos\theta + 3\sin\theta} \qquad (10)$$

$$y = \frac{\sin\theta}{\sqrt{3}\cos\theta + 3\sin\theta} \qquad (11)$$

$$z = \tfrac{1}{12}\sqrt{6}. \qquad (12)$$

The polar angle ϕ can then be solved for as a function of θ as

$$\phi(\theta) = \cos^{-1}\left(\frac{z}{\sqrt{x^2+y^2+z^2}}\right)$$

$$= \tan^{-1}\left(\frac{2\sqrt{6}}{\sqrt{3}\cos\theta + 3\sin\theta}\right). \qquad (13)$$

The integral over ϕ can be done by making the

change of coordinates

$$u = \frac{2\sqrt{6}}{\sqrt{3}\cos\theta + 3\sin\theta}, \tag{14}$$

giving

$$V = \int_0^{\pi/3} \tfrac{1}{32}\Big[256 - 45\sqrt{6} + 42\sqrt{6}\cos(2\tan^{-1}u)$$

$$-\frac{58\sqrt{13+3\cos(2\tan^{-1}u)}}{\sqrt{1+u^2}}$$

$$+6\sqrt{13+3\cos(2\tan^{-1}u)}\cos(3\tan^{-1}u)$$

$$+3\sqrt{6}\cos(4\tan^{-1}u)\Big]\,d\theta. \tag{15}$$

Making the change of variables

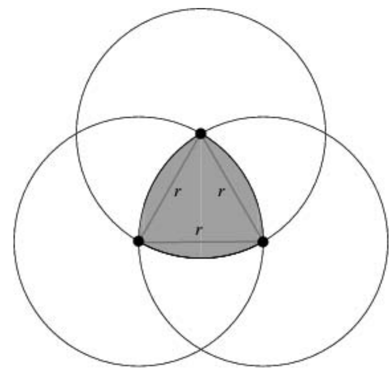
$$u = \frac{2\sqrt{6}(1+3t^2)}{\sqrt{3}+3\sqrt{3}t} \tag{16}$$

then gives the volume as

$$V = \int_0^1 \left(\frac{8\sqrt{3}}{1+3t^2} - \frac{16\sqrt{2}(3t+1)(4t^2+t+1)^{3/2}}{(3t^2+1)(11t^2+2t+3)^2}\right.$$

$$\left.-\frac{\sqrt{2}(249t^2+54t+65)}{(11t^2+2t+3)^2}\right)dt. \tag{17}$$

This integral can be done analytically, but the analytic form returned by symbolic algebra programs is an extremely complicated expression involving logarithms and inverse tangent functions. After arduous simplification of the expression by hand, the final solution



$$V = \tfrac{1}{24}\left[6\sqrt{2} + 16\pi + 57\cos^{-1}\left(\tfrac{17}{81}\right) - 132\tan^{-1}\left(\sqrt{2}\right)\right] \tag{18}$$

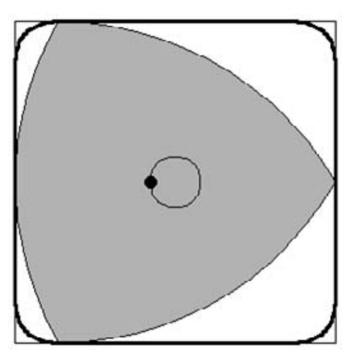
$$\approx 0.422157733 \tag{19}$$

is obtained. This solution appears not to have been published previously.

See also Hyperbolic Tetrahedron, Reuleaux Triangle, Sphere, Sphere-Sphere Intersection, Spherical Triangle, Steinmetz Solid, Tetrahedron

Reuleaux Triangle

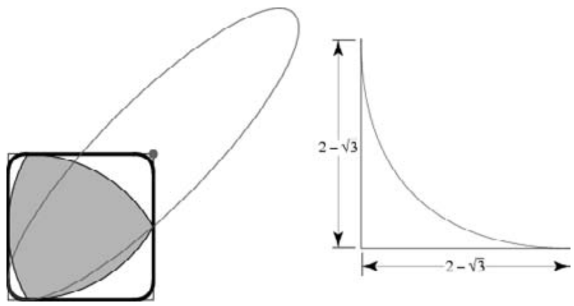
A curve of constant width constructed by drawing arcs from each vertex of an equilateral triangle between the other two vertices. The Reuleaux triangle has the smallest area for a given width of any curve of constant width. Let the arc radius be r. Since the area of each meniscus-shaped portion of the Reuleaux triangle is a circular segment with opening angle $\theta = \pi/3$,



$$A_s = \tfrac{1}{2}r^2(\theta - \sin\theta) = \left(\frac{\pi}{6} - \frac{\sqrt{3}}{4}\right)r^2. \tag{1}$$

But the area of the central equilateral triangle with $a = 1/\sqrt{3}$ is

$$A_t = \tfrac{1}{4}\sqrt{3}r^2, \tag{2}$$



so the total area is then

$$A = 3A_s + A_t = \tfrac{1}{2}\left(\pi - \sqrt{3}\right)r^2. \tag{3}$$

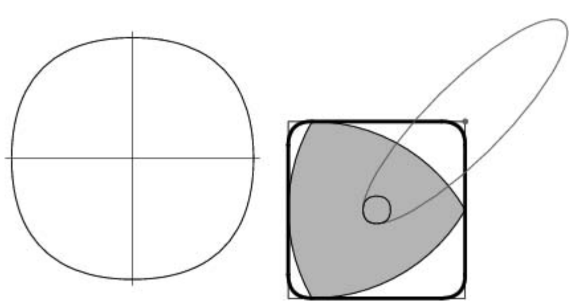
Because it can be rotated inside a square, as illustrated above, it is the basis for the Harry Watt

square drill bit.

When rotated inside a square of side length 2 having corners at $(\pm1,\ \pm1)$, the envelope of the Reuleaux triangle is a region of the square with rounded corners. At the corner $(-1,\ -1)$, the envelope of the boundary is given by the segment of the ellipse with PARAMETRIC EQUATIONS

$$x = 1 - \cos\beta - \sqrt{3}\,\sin\beta \tag{4}$$

$$y = 1 - \sin\beta - \sqrt{3}\,\cos\beta \tag{5}$$



for $\beta \in [\pi/6,\ \pi/3]$, extending a distance $2-\sqrt{3}$ from the corner (Gleißner and Zeitler 2000). The ellipse has center (1, 1), semimajor axis $a = 1+\sqrt{3}$, semiminor axis $b = 1-\sqrt{3}$, and is rotated by 45°, which has Cartesian equation

$$x^2 + y^2 - \sqrt{3}xy - \left(2-\sqrt{3}\right)x - \left(2-\sqrt{3}\right)y + 1 - \sqrt{3} = 0. \tag{6}$$

The fractional AREA covered as the Reuleaux triangle rotates is

$$A_{\text{covered}} = 2\sqrt{3} + \tfrac{1}{6}\pi - 3 = 0.9877003907\ldots. \tag{7}$$

Note that Gleißner and Zeitler (2000) fail to simplify their equivalent equation, and then proceed to assert that (7) is erroneous.

The CENTROID does *not* stay fixed as the TRIANGLE is rotated, nor does it move along a CIRCLE. In fact, the path consists of a curve composed of four arcs of an ELLIPSE (Wagon 1991). For a bounding square of side length 2, the ellipse in the lower-left quadrant has PARAMETRIC EQUATIONS

$$x = 1 + \cos\beta + \tfrac{1}{3}\sqrt{3}\sin\beta \tag{8}$$

$$y = 1 + \sin\beta + \tfrac{1}{3}\sqrt{3}\cos\beta \tag{9}$$

for $\beta \in [\pi/6,\ \pi/3]$. The ellipse has center (1, 1), semimajor axis $a = 1 + 1/\sqrt{3}$, semiminor axis $b = 1 - 1/\sqrt{3}$, and is rotated by 45°, which has Cartesian equation

$$3x^2 + 3y^2 - 3\sqrt{3}xy - 3x\left(2+\sqrt{3}\right) - 3y\left(2+\sqrt{3}\right) + 5 - 3\sqrt{3} = 0. \tag{10}$$

The area enclosed by the locus of the centroid is given by

$$A_{\text{centroid}} = 4 - \tfrac{8}{3}\sqrt{3} + \tfrac{2}{9}\pi \tag{11}$$

(Gleißner and Zeitler 2000; who again fail to simplify their expression). Note that the CENTROID's path can be closely approximated by a SUPERELLIPSE

$$\left|\frac{x}{a}\right|^r + \left|\frac{y}{a}\right|^r = 1 \tag{12}$$

with $a = 2\sqrt{3}/3 - 1$ and $r \approx 2.36185$.

Reversal

The reversal of a decimal number $abc\cdots$ is $\cdots cba$. Ball and Coxeter (1987) consider numbers whose reversals are integral multiples of themselves. PALINDROMIC NUMBERS and numbers ending with a ZERO are trivial examples.

The first few nontrivial examples are 8712, 9801, 87912, 98901, 879912, 989901, 8799912, 9899901, 87128712, 87999912, 98019801, 98999901, ... (Sloane's A031877). The pattern continues for large numbers, with numbers OF THE FORM $87\underbrace{9\cdots9}12$ equal to 4 times their reversals and numbers OF THE FORM $98\underbrace{9\cdots9}01$ equal to 9 times their reversals. In addition, runs of numbers of either of these forms can be concatenated to yield numbers OF THE FORM $87\underbrace{9\cdots9}12\cdots87\underbrace{9\cdots9}12$, equal to 4 times their reversals, and $98\underbrace{9\cdots9}01\cdots98\underbrace{9\cdots9}01$, equal to 9 times their reversals.

The product of a 2-digit number and its reversal is never a SQUARE NUMBER except when the digits are the same (Ogilvy 1988). Numbers whose product is the reversal of the products of their reversals include (221, 312) and (122, 213), since

$$312\times221=68952$$

$$213\times122=25986$$

(Ball and Coxeter 1987, p. 14).

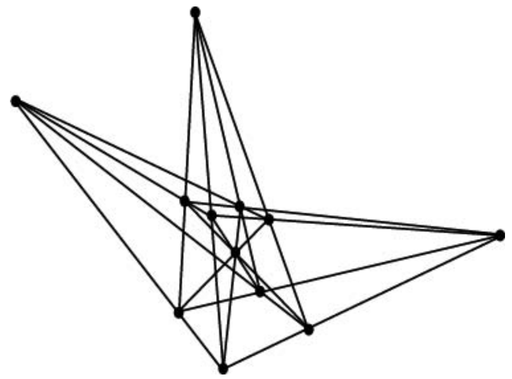
SERIES REVERSION

Reversion to the Mean

This entry contributed by ANTON E. WEISSTEIN

Reversion to the mean is the statistical phenomenon that a random variate which deviates strongly from the mean in a particular direction is likely to be succeeded by an event (independent of the first) that deviates less far in this direction. In other words, an extreme event is likely to be followed by a less extreme event.



Although this phenomenon appears to violate the definition of INDEPENDENT EVENTS, it simply reflects the fact that there are more values from which to choose on the side of the probability distribution closer to the mean than there are on the side corresponding to even more extreme values.

See also MEAN

Reye's Configuration

A configuration of 12 planes and 12 points such that six points lie in every plane and six planes pass through every point. Alternatively, the configuration consists of 16 lines and the same 12 points such that four lines pass through every point and three points lie on every line.

The points consist of the eight vertices of a CUBE together with its center and the three POINTS AT INFINITY where parallel edges of the CUBE meet. The 12 planes are the six faces of the cube and the six planes passing through diagonally opposite edges. The 16 lines consist of the 12 edges and four space diagonals of the cube.

Reye's configuration can be realized without any points at infinity by squashing the cube and bringing the points at infinity to finite positions, as illustrated above.

Reznik's Identity

For P and Q POLYNOMIALS in n variables,

$$|P \cdot Q|_2^2 = \sum_{i_1,\ \dots,\ i_n \geq 0} \times \frac{|P^{(i_1,\ \dots,\ i_n)}(D_1,\ \dots,\ D_n)Q(x_1,\ \dots,\ x_n)|_2^2}{i_1! \cdots i_n!},$$

where $D_i \equiv \partial/\partial x_i$, $|X|_2$ is the BOMBIERI NORM, and

$$P^{(i_1,\ \dots,\ i_n)} = D_1^{i_1} \cdots D_n^{i_n} P.$$

BOMBIERI'S INEQUALITY follows from this identity.

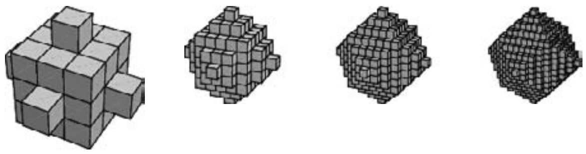
See also BEAUZAMY AND DÉGOT'S IDENTITY

Rhodonea

ROSE

Rhomb

RHOMBUS



Rhombic Dodecahedral Number

A FIGURATE NUMBER which is constructed as a centered CUBE with a SQUARE PYRAMID appended to each face,

$$\begin{aligned} RhoDod_n &= CCub_n + 6P_{n-1} \\ &= (2n-1)(2n^2-2n+1), \end{aligned} \quad (1)$$

where $CCub_n$ is a CENTERED CUBE NUMBER and P_n is a PYRAMIDAL NUMBER. The first few are 1, 15, 65, 175, 369, 671, ... (Sloane's A005917). The GENERATING FUNCTION of the rhombic dodecahedral numbers is

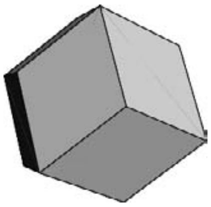
$$\frac{x(1+11x+11x^2+x^3)}{(x-1)^4} = x + 15x^2 + 65x^3 + 175x^4 + \dots. \quad (2)$$

A related set of numbers is the number of cubes in the HAUY CONSTRUCTION of the RHOMBIC DODECAHEDRON, given by

$$HauyRhoDod_k = k^3 + 6 \sum_{i=1,\ 3,\ \dots,\ k-2} i^2, \quad (3)$$

for k an ODD NUMBER. Re-indexing with $k = 2n-1$ then gives

$$HauyRhoDod_n = (2n-1)(8n^2-14n+7), \quad (4)$$



giving the first few values 1, 33, 185, 553, 1233, ... (Sloane's A046142).

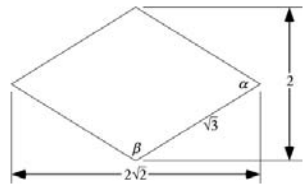
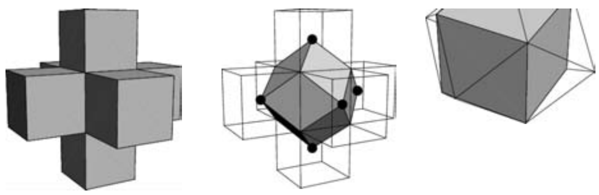
Rhombic Dodecahedron

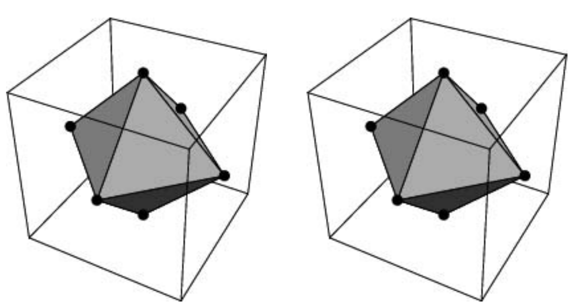


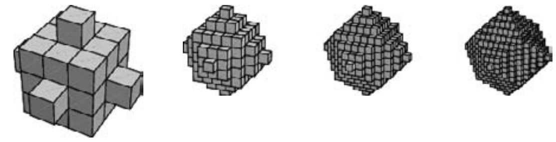


The DUAL POLYHEDRON of the CUBOCTAHEDRON A_1 and Wenninger dual W_{11}. Its sometimes also called the RHOMBOIDAL DODECAHEDRON (Cotton 1990). Its 14 vertices are joined by 12 RHOMBUSES of the dimensions shown in the figure below, where

$$\alpha = 2\cot^{-1}\sqrt{2} = \cos^{-1}\left(\tfrac{1}{3}\right) \approx 70.53° \quad (1)$$

$$\beta = 2\tan^{-1}\sqrt{2} \approx 109.47°. \quad (2)$$





The rhombic dodecahedron can be built up by a placing six cubes on the faces of a seventh, in the configuration of a metal "jack." Joining the centers of the outer cubes with the vertices of the central cube then gives the rhombic dodecahedron. Affixing a SQUARE PYRAMID of height 1/2 on each face of a CUBE having unit edge length results in a rhombic dodecahedron (Brückner 1900, p. 130; Steinhaus 1983, p. 185).

If the rhombic dodecahedron is hinged into six square pyramids along three consecutive face diagonals, the resulting model can be folded into a cube (Wells 1991). One possible construction for the rhombic dodecahedron is known as the BAUSPIEL. It can also be constructed by CUMULATION of a unit edge-length CUBE by a pyramid with height 1/2.

The rhombic dodecahedron is a ZONOHEDRON and a SPACE-FILLING POLYHEDRON (Steinhaus 1983, p. 185). The vertices are given by $(\pm 1, \pm 1, \pm 1)$, $(\pm 2, 0, 0)$, $(0, \pm 2, 0)$, $(0, 0, \pm 2)$.

The edges of the CUBE-OCTAHEDRON COMPOUND intersecting in the points plotted above are the diagonals of RHOMBUSES, and the 12 RHOMBUSES form a rhombic dodecahedron (Ball and Coxeter 1987). There are three stellations of the rhombic dodecahedron.

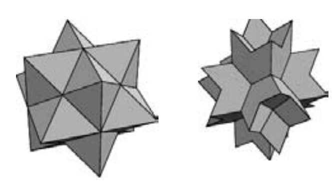
The rhombic dodecahedron can be built using a HAUY CONSTRUCTION. The Hauy RHOMBIC DODECAHEDRAL NUMBERS

$$HRhoDod_n = (2n-1)(8n^2 - 14n + 7) \tag{3}$$

give a method for calculating the VOLUME of the rhombic dodecahedron,

$$V = \lim_{n\to\infty} HRhoDod_n \left(\frac{a}{n\sqrt{3}}\right)^3 = \tfrac{16}{9}\sqrt{3}a^3 \tag{4}$$

(Steinhaus 1983). The SURFACE AREA of a rhombic dodecahedron with unit edge length is



$$S = 8\sqrt{2}. \tag{5}$$

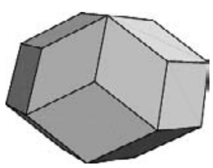
Rhombic Dodecahedron Stellations



There are three STELLATIONS of the RHOMBIC DODECAHEDRON (Wells 1991), two of which are illustrated above. The first stellation can be constructed by drawing diagonals across the square faces of a CUBOCTAHEDRON and connecting centers of these diagonals with the vertices of neighboring squares. The outer edges of the second stellation correspond with those of the TRUNCATED OCTAHEDRON.

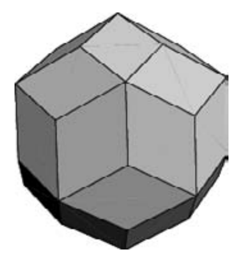
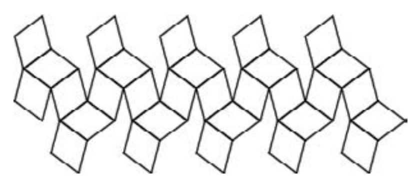
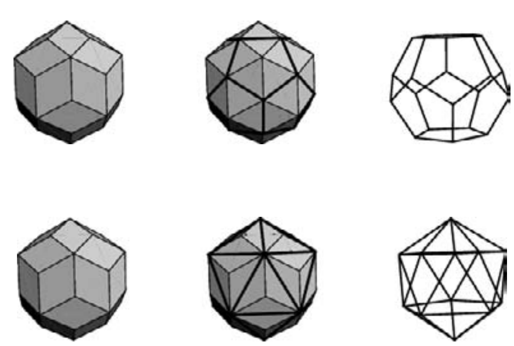
Rhombic Spirallohedron





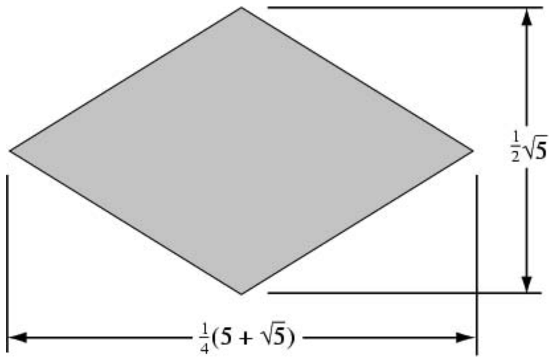
A beautiful class of polyhedra composed of rhombic faces discovered accidentally by R. Towle while attempting to develop a function to create a rhombic hexahedron from a triple of vectors.

References



Towle, R. "Rhombic Spirallohedra." http://www.mathsource.com/cgi-bin/msitem?0208–718.

Rhombic Triacontahedron



A ZONOHEDRON which is the DUAL POLYHEDRON of the ICOSIDODECAHEDRON A_4 and Wenninger dual W_{12}. It is composed of 30 RHOMBI joined at 32 vertices. The intersecting edges of the DODECAHEDRON-ICOSAHEDRON COMPOUND form the diagonals of 30 RHOMBI which comprise the TRIACONTAHEDRON. The CUBE 5-COMPOUND has the 30 facial planes of the rhombic triacontahedron (Wenninger 1983, p. 36; Ball and Coxeter 1987).

The short diagonals of the faces of the rhombic triacontahedron give the edges of a DODECAHEDRON, while the long diagonals give the edges of the ICOSAHEDRON (Steinhaus 1983, pp. 209–210). Taken

together, the DODECAHEDRON and ICOSAHEDRON give a DODECAHEDRON-ICOSAHEDRON COMPOUND.

The rhombic triacontahedron generated from an ICOSIDODECAHEDRON of unit edge lengths has edge lengths

$$s = \tfrac{1}{4}\sqrt{\tfrac{5}{2}\left(5+\sqrt{5}\right)}. \qquad (1)$$

and INRADIUS

$$r = \tfrac{1}{8}\left(5+3\sqrt{5}\right). \qquad (2)$$

Normalizing so that $s = 1$, the solid has SURFACE AREA and VOLUME given by

$$S = 12\sqrt{5} \qquad (3)$$

$$V = 4\sqrt{5+2\sqrt{5}}. \qquad (4)$$

Rhombic Triacontahedron Stellations

Ede (1958) enumerates 13 basic series of stellations of the rhombic triacontahedron, the total number of which is extremely large. Pawsey (1973) gave a set of restrictions upon which a complete enumeration of stellations can be achieved (Wenninger 1983, p. 36). Messer (1995) describes 226 stellations, some of which are illustrated above.

The CONVEX HULL of the DODECADODECAHEDRON is an ICOSIDODECAHEDRON and the dual of the ICOSIDODECAHEDRON is the RHOMBIC TRIACONTAHEDRON, so the dual of the DODECADODECAHEDRON (the MEDIAL RHOMBIC TRIACONTAHEDRON) is one of the rhombic triacontahedron stellations (Wenninger 1983, p. 41). Another is the GREAT RHOMBIC TRIACONTAHEDRON.

Rhumb Line

LOXODROME

Ribbon Knot

If the KNOT K is the boundary $K = f(\mathbb{S}^1)$ of a singular disk $f: \mathbb{D} \to \mathbb{S}^3$ which has the property that each self-intersecting component is an arc $A \subset f(\mathbb{D}^2)$ for which $f^{-1}(A)$ consists of two arcs in $\mathbb{D}^2$, one of which is interior, then K is said to be a ribbon knot. Every ribbon knot is a SLICE KNOT, and it is conjectured that every SLICE KNOT is a ribbon knot.

See also SLICE KNOT

References

Ribet's Theorem

If the TANIYAMA-SHIMURA CONJECTURE holds for all semistable ELLIPTIC CURVES, then FERMAT'S LAST THEOREM is true. Before its proof by Ribet in 1986, the theorem had been called the EPSILON CONJECTURE. It had its roots in a surprising result of G. Frey.

See also ELLIPTIC CURVE, EPSILON CONJECTURE, FERMAT'S LAST THEOREM, MODULAR FORM, MODULAR FUNCTION, TANIYAMA-SHIMURA CONJECTURE

Riccati Differential Equation

$$y' = P(z) + Q(z)y + R(z)y^2, \tag{1}$$

where $y' \equiv dy/dz$. The transformation

$$w \equiv -\frac{y'}{yR(z)} \tag{2}$$

leads to the second-order linear homogeneous equation

$$R(z)y'' - [R'(z) + Q(z)R(z)]y' + [R(z)]^2 P(z)y = 0. \tag{3}$$

Another equation sometimes called the Riccati differential equation is

$$z^2 w'' + \left[z^2 - n(n+1)\right]w = 0 \tag{4}$$

(Zwillinger 1997, p. 126), which has solutions

$$w = Azj_n(z) + Bzy_n(z), \tag{5}$$

where $j_n(z)$ and $y_n(z)$ are SPHERICAL BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS.

Yet another form of "the" Riccati differential equation is

$$\frac{dy}{dz} = az^n + by^2, \tag{6}$$

which is solvable by algebraic, exponential, and logarithmic functions only when $n = -4m/(2m \pm 1)$, for $m = 0, 1, 2, ...$

Riemann Curve Theorem

If two algebraic plane curves with only ordinary singular points and CUSPS are related such that the coordinates of a point on either are RATIONAL FUNCTIONS of a corresponding point on the other, then the curves have the same GENUS (CURVE). This can be stated equivalently as the GENUS of a curve is unaltered by a BIRATIONAL TRANSFORMATION.

Riemann Function

There are a number of functions in various branches of mathematics known as Riemann functions. Examples include the RIEMANN P-SERIES, RIEMANN-SIEGEL FUNCTIONS, RIEMANN THETA FUNCTION, RIEMANN

ZETA FUNCTION, XI FUNCTION, the function $F(x)$ obtained by Riemann in studying FOURIER SERIES, the function $R(x, y; \xi, \eta)$ appearing in the application of the RIEMANN METHOD for solving the GOURSAT PROBLEM, the function $R(n)$ in the RIEMANN PRIME NUMBER FORMULA, and the function $f(x)$ related to the PRIME COUNTING FUNCTION defined below.

The Riemann function $F(x)$ for a FOURIER SERIES

$$\tfrac{1}{2}a_0 + \sum_{n=1}^{\infty}[a_n \cos(nx) + b_n \sin(nx)] \tag{1}$$

is obtained by integrating twice term by term to obtain

$$F(x) = \tfrac{1}{4}a_0x^2 - \sum_{n=1}^{\infty}\frac{1}{n^2}[a_n\cos(nx) + b_n \sin(nx)] + Cx + D, \tag{2}$$

where C and D are constants (Riemann 1957; Hazewinkel 1988, vol. 8, p. 118).

The Riemann function $R(x, y; \xi, \eta)$ arises in the solution of the linear case of the GOURSAT PROBLEM of solving the HYPERBOLIC PARTIAL DIFFERENTIAL EQUATION

$$\tilde{L}u = u_{xy} + au_x + bu_y + cu = f \tag{3}$$

with BOUNDARY CONDITIONS

$$u(0, t) = \phi(t) \tag{4}$$

$$u(t, 1) = \psi(t) \tag{5}$$

$$\phi(1) = \phi(0). \tag{6}$$

Here, $R(x, y; \xi, \eta)$ is defined as the solution of the equation

$$R_{xy} - (aR)_x - (bR)_y + cR = 0 \tag{7}$$

which satisfies the conditions

$$R(\xi, y; \xi, n) = \exp\left[\int_{\eta}^{y} a(\xi, t)\, dt\right] \tag{8}$$

$$R(x, \eta; \xi, \eta) = \exp\left[\int_{\xi}^{x} b(t, \eta)\, dt\right] \tag{9}$$

on the characteristics $x = \xi$ and $y = \eta$, where (ξ, η) is a point on the domain Ω on which (8) is defined (Hazewinkel 1988). The solution is then given by the RIEMANN FORMULA

$$u(x, y) = \int_0^x d\xi \int_1^y R(\xi, \eta; x, y) f(\xi, \eta)\, d\eta. \tag{10}$$

This method of solution is called the RIEMANN METHOD.

Riemann defined the function $f(x)$ by

$$f(x) \equiv \sum_{n=1}^{\infty}\frac{\pi(x^{1/n})}{n} = \pi(x) + \tfrac{1}{2}\pi(x^{1/2}) + \tfrac{1}{3}\pi(x^{1/3}) + \ldots \tag{11}$$

(Hardy 1999, p. 30), then the PRIME COUNTING FUNCTION $\pi(x)$ is related to $f(x)$ by

$$\pi(x) = \sum_{n=1}^{\infty}\frac{\mu(n)}{n} f(x^{1/n}), \tag{12}$$

where $\mu(n)$ is the MÖBIUS FUNCTION (Riesel 1994, p. 49). Riemann (1859) proposed that

$$f(x) = \mathrm{li}(x) - \sum_{\rho}\mathrm{li}(x^{\rho}) - \ln 2 + \int_x^{\infty}\frac{dt}{t \ln t(t^2 - 1)}, \tag{13}$$

where $\mathrm{li}(x)$ is the LOGARITHMIC INTEGRAL and the sum is over all nontrivial zeros ρ of the RIEMANN ZETA FUNCTION $\zeta(z)$ (Mathews 1892, Ch. 10; Landau 1974, Ch. 19; Ingham 1990, Ch. 4; Hardy 1999, p. 40). This formula was subsequently proved by Mangoldt in 1895 (Riesel 1994, p. 47).

A function related to $f(x)$ is given by

$$J(x) \equiv \begin{cases} \pi(x) + \tfrac{1}{2}\pi(x^{1/2}) + \tfrac{1}{3}\pi(x^{1/3}) + \ldots - \tfrac{1}{2m} \\ \quad \text{for } p^m \text{ with } p \text{ prime} \\ \pi(x) + \tfrac{1}{2}\pi(x^{1/2}) + \tfrac{1}{3}\pi(x^{1/3}) + \ldots \\ \quad \text{otherwise} \end{cases} \tag{14}$$

$$= \lim_{t\to\infty}\frac{1}{2\pi i}\int_{2-iT}^{2+iT}\frac{x^s}{s}\ln\zeta(s)\, ds, \tag{15}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. This function satisfies

$$\frac{\ln\zeta(s)}{s} = \int_1^{\infty} J(x)x^{-s-1}\, dx \tag{16}$$

(Riesel 1994, p. 47).

Riemann Hypothesis

First published in Riemann (1859), the Riemann hypothesis states that the nontrivial ROOTS of the RIEMANN ZETA FUNCTION

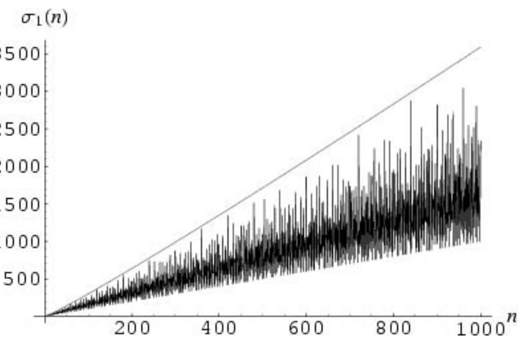
$$\zeta(s) \equiv \sum_{n=1}^{\infty} \frac{1}{n^s}, \tag{1}$$

where $x \in \mathbb{C}$ (the COMPLEX NUMBERS), all lie on the "CRITICAL LINE" $\Re[s] = 1/2$, where $\Re[z]$ denotes the REAL PART of z. The Riemann hypothesis is also known as ARTIN'S CONJECTURE. Wiener showed that the PRIME NUMBER THEOREM is literally equivalent to the assertion that $\zeta(s)$ has no zeros on $\sigma = 1$ (Hardy 1999, pp. 34 and 58–60).

In 1914, Hardy proved that an INFINITE number of values for s can be found for which $\zeta(s) = 0$ and $\Re[s] = 1/2$. However, it is not known if *all* nontrivial roots s satisfy $\Re[s] = 1/2$, so the conjecture remains open. André Weil proved the Riemann hypothesis to be true for field functions (Weil 1948, Eichler 1966, Ball and Coxeter 1987). In 1974, Levinson (1974ab) showed that at least 1/3 of the ROOTS must lie on the CRITICAL LINE (Le Lionnais 1983), a result which has since been sharpened to 40% (Vardi 1991, p. 142). It is known that the zeros are symmetrical placed about the line $\Im[s] = 0$.

The Riemann hypothesis is equivalent to $\Lambda \leq 0$, where Λ is the DE BRUIJN-NEWMAN CONSTANT (Csordas *et al.* 1994). It is also equivalent to the assertion that for some constant c,

$$|\mathrm{Li}(x) - \pi(x)| \leq c\sqrt{x} \ln x, \tag{2}$$



where $\mathrm{Li}(x)$ is the LOGARITHMIC INTEGRAL and π is the PRIME COUNTING FUNCTION (Wagon 1991). Another equivalent form states that

$$\mathrm{span}_{L^2(0,\,1)}\{\rho_\alpha,\ 0 < \alpha < 1\} = L^2(0,\ 1), \tag{3}$$

where

$$\rho_\alpha(t) \equiv \mathrm{frac}\left(\frac{\alpha}{t}\right) - \alpha\,\mathrm{frac}\left(\frac{1}{t}\right), \tag{4}$$

where $\mathrm{frac}(x)$ is the FRACTIONAL PART (Balazard and Saias 2000).

By modifying a criterion of Robin (1984), Lagarias (2000) showed that the Riemann hypothesis is equivalent to the statement that

$$\sigma(n) \leq H_n + \exp(H_n) \ln H_n, \tag{5}$$

for all $n \geq 1$, with equality only for $n = 1$, where H_n is a HARMONIC NUMBER and $\sigma(n)$ is the DIVISOR FUNCTION.

There is also a finite analog of the Riemann hypothesis concerning the location of zeros for function fields defined by equations such as

$$ay^l + bz^m + c = 0. \tag{6}$$

This hypothesis, developed by Weil, is analogous to the usual Riemann hypothesis. The number of solutions for the particular cases $(l,\ m) = (2,\ 2)$, $(3,\ 3)$, $(4,\ 4)$, and $(2,\ 4)$ were known to Gauss.

The hypothesis has thus far resisted all attempts to prove it, although it has been computationally tested and found to be true for the first $200,000,001$ zeros by Brent *et al.* (1982). Brent's calculation covered zeros $\sigma + it$ in the region $0 < t < 81,\ 702,\ 130.19$. In 2000, Clay Mathematics Institute offered a \$1 million prize for proof of the Riemann hypothesis.

Riemann Integral

The Riemann integral is the INTEGRAL normally encountered in CALCULUS texts and used by physicists and engineers. Other types of integrals exist (e.g., the LEBESGUE INTEGRAL), but are unlikely to be encountered outside the confines of advanced mathematics texts. In fact, according to Jeffreys and Jeffreys (1988, p. 29), "it appears that cases where these methods [i.e., generalizations of the Riemann integral] are applicable and Riemann's [definition of the integral] is not are too rare in physics to repay the extra difficulty."

The Riemann integral is based on the JORDAN MEASURE, and defined by taking a limit of a RIEMANN SUM,

$$\int_b^a f(x)\,dx \equiv \lim_{\max\,\Delta x_k\to 0} \sum_{k=1}^n f(x_k^*)\Delta x_k \tag{1}$$

$$\iint f(x,\ y)\,dA \equiv \lim_{\max\,\Delta A_k\to 0} \sum_{k=1}^n f(x_k^*,\ y_k^*)\Delta A_k \tag{2}$$

$$\iiint f(x,\ y\ z)\,dV \equiv \lim_{\max\,\Delta V_k\to 0} \sum_{k=1}^n f(x_k^*,\ y_k^*, z_k^*)\Delta V_k, \tag{3}$$

where $a \le x \le b$ and x_k^*, y_k^*, and z_k^* are arbitrary points in the intervals Δx_k, Δy_k, and Δz_k, respectively. The value $\max\Delta x_k$ is called the MESH SIZE of a partition of the interval $[a,\ b]$ into subintervals Δx_k.

As an example of the application of the Riemann integral definition, find the AREA under the curve $y = x^r$ from 0 to a. Divide $(a,\ b)$ into n segments, so $\Delta x_k = \frac{b-a}{n} \equiv h$, then

$$f(x_1) = f(0) = 0 \tag{4}$$

$$f(x_2) = f(\Delta x_k) = h^r \tag{5}$$

$$f(x_3) = f(2\Delta x_k) = (2h)^r. \tag{6}$$

By induction

$$f(x_k) = f([k-1]\Delta x_k) = [(k-1)h]^r = h^r(k-1)^r, \tag{7}$$

so

$$f(x_k)\Delta x_k = h^{r+1}(k-1)^r \tag{8}$$

$$\sum_{k=1}^n f(x_k)\Delta x_k = h^{r+1}\sum_{k=1}^n (k-1)^r. \tag{9}$$

For example, take $r = 2$.

$$\sum_{k=1}^n f(x_k)\Delta x_k = h^3 \sum_{k=1}^n (k-1)^2$$

$$= h^3\left(\sum_{k=1}^n k^2 - 2\sum_{k=1}^n k + \sum_{k=1}^n 1\right)$$

$$= h^3\left[\frac{n(n+1)(2n+1)}{6} - 2\,\frac{n(n+1)}{2} + n\right], \tag{10}$$

so

$$I \equiv \lim_{n\to\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x_k = \lim_{n\to\infty} \sum_{k=1}^{n} f(x_k)\Delta x_k$$

$$= \lim_{n\to\infty} h^3 \left[\frac{n(n+1)(2n+1)}{6} - 2\,\frac{n(n+1)}{2} + n\right]$$

$$= a^3 \lim_{n\to\infty} \left[\frac{n(n+1)(2n+1)}{6n^3} - \frac{n(n+1)}{n^3} + \frac{n}{n^3}\right]$$

$$= \tfrac{1}{3} a^3. \tag{11}$$

Riemann Mapping Theorem

Let z_0 be a point in a simply connected region $R \neq \mathbb{C}$. Then there is a unique analytic function $w = f(z)$ mapping R one-to-one onto the disk $|w| < 1$ such that $f(z_0) = 0$ and $f'(z_0) = 0$. The corollary guarantees that any two simply connected regions except $\mathbb{R}^2$ can be mapped conformally onto each other.

Riemann P-Differential Equation

The differential equation

$$\frac{d^2u}{dz^2} + \left[\frac{1-\alpha-\alpha'}{z-a} + \frac{1-\beta-\beta'}{z-b} + \frac{1-\gamma-\gamma'}{z-c}\right]\frac{du}{dz}$$
$$+ \left[\frac{\alpha\alpha'(a-b)(a-c)}{z-a} + \frac{\beta\beta'(b-c)(b-a)}{z-b} + \frac{\gamma\gamma'(c-a)(c-b)}{z-c}\right]\frac{u}{(z-a)(z-b)(z-c)} = 0,$$

where

$$\alpha + \alpha' + \beta + \beta' + \gamma + \gamma' = 1,$$

first obtained in the form by Papperitz (1885; Bares 1908). Solutions are Riemann P-series (Abramowitz and Stegun 1972, pp. 564–565). Zwillinger (1995, p. 414) confusingly calls this equation the "hypergeometric equation."

Riemann Prime Number Formula

Riemann considered

$$R(x) = \sum_{n=1}^{\infty} \frac{\mu(n)}{n} \operatorname{li}\left(x^{1/n}\right), \tag{1}$$

obtained by replacing $f\left(x^{1/n}\right)$ in the Riemann function with the logarithmic integral $\operatorname{li}\left(x^{1/n}\right)$., where $\zeta(z)$ is the Riemann zeta function and $\mu(n)$ is the Möbius function (Hardy 1999, pp. 16 and 23). This

series is identical to the GRAM SERIES (Hardy 1999, pp. 24–25). The quantity $R(x)-\pi(x)$ is plotted above. In addition,

$$\pi(x)=R(x)-\sum_{\rho} R(x^{\rho}), \tag{2}$$

where $\pi(x)$ is the PRIME COUNTING FUNCTION and the SUM is over all complex (nontrivial) zeros ρ of $\zeta(s)$, i.e., those in the CRITICAL STRIP so $0<\Re[\rho]<1$, interpreted to mean

$$\sum_{\rho} R(x^{\rho})=\lim_{t\to\infty}\sum_{|\Im(\rho)|<t} R(x^{\rho}). \tag{3}$$

Riemann conjectured that $R(n)=\pi(n)$ (Knuth 1998, p. 382), but this was disproved by Littlewood in 1914 (Hardy and Littlewood 1918).

Ramanujan independently derived the formula for $R(n)$, but nonrigorously (Berndt 1994, p. 123; Hardy 1999, p. 23). The following table compares $\pi(x)$, li x, and $R(x)$ for small x. Note that the values given by Hardy (1999, p. 26) for $x=10^9$ are incorrect.

x	$\pi(x)$	$\mathrm{li}(x)-\pi(x)$	$R(x)-\pi(x)$
100000	9592	38	−5
1000000	78498	130	29
2000000	148933	122	−9
3000000	216816	155	0
4000000	283146	206	33
5000000	348513	125	−64
6000000	412849	228	24
7000000	476648	179	−38
8000000	539777	223	−6
9000000	602489	187	−53
10000000	664579	339	88
100000000	5761455	754	97
1000000000	50847534	1701	−79

Riemann P-Series

The solutions to the RIEMANN P-DIFFERENTIAL EQUATION

$$z\equiv P\left\{\begin{matrix} a & b & c & \\ \alpha & \beta & \gamma; & z \\ \alpha' & \beta' & \gamma' & \end{matrix}\right\}.$$

Solutions are given in terms of the HYPERGEOMETRIC FUNCTION by

$$u_1=\left(\frac{z-a}{z-b}\right)^{\alpha}\left(\frac{z-c}{z-b}\right)^{\gamma} {}_2F_1(\alpha+\beta+\gamma,\ \alpha+\beta'+\gamma;\ 1+\alpha-\alpha';\ \lambda)$$

$$u_2=\left(\frac{z-a}{z-b}\right)^{\alpha'}\left(\frac{z-c}{z-b}\right)^{\gamma} {}_2F_1(\alpha'+\beta+\gamma,\ \alpha'+\beta'+\gamma;\ 1+\alpha'-\alpha;\ \lambda)$$

$$u_3=\left(\frac{z-a}{z-b}\right)^{\alpha}\left(\frac{z-c}{z-b}\right)^{\gamma'} {}_2F_1(\alpha+\beta+\gamma',\ \alpha+\beta'+\gamma';\ 1+\alpha-\alpha';\ \lambda)$$

$$u_4=\left(\frac{z-a}{z-b}\right)^{\alpha'}\left(\frac{z-c}{z-b}\right)^{\gamma'} {}_2F_1(\alpha'+\beta+\gamma',\ \alpha'+\beta'+\gamma';\ 1+\alpha'-\alpha;\ \lambda)$$

where

$$\lambda=\frac{(z-a)(c-b)}{(z-b)(c-a)}.$$

Riemann Removable Singularity Theorem

Let $f : D(z_0, r)\backslash\{z_0\} \to \mathbb{C}$ be ANALYTIC and bounded on a PUNCTURED OPEN DISK $D(z_0, r)$, then $\lim_{z\to z_0} f(z)$ exists, and the function defined by $\tilde{f} : D(z_0, r) \to \mathbb{C}$

$$\tilde{f}(z) = \begin{cases} f(z) & \text{for } z \neq z_0 \\ \lim_{z'\to z_0} f(z') & \text{for } z = z_0 \end{cases}$$

is ANALYTIC.

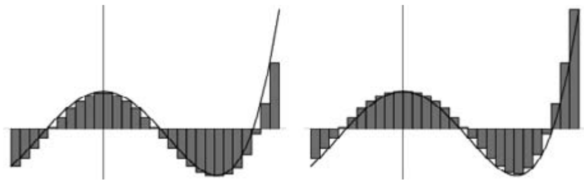
Riemann Space

METRIC SPACE

Riemann Sphere



A 1-D COMPLEX MANIFOLD C*, which is the one-point COMPACTIFICATION of the COMPLEX NUMBERS $\mathbb{C}^* = \mathbb{C} \cup \{\infty\}$, together with two charts. (Here [522, ∞] denoted COMPLEX INFINITY). For all points in the COMPLEX PLANE, the chart is the IDENTITY MAP from the SPHERE (with infinity removed) to the COMPLEX PLANE. For the POINT AT INFINITY, the chart neighborhood is the sphere (with the ORIGIN removed), and the chart is given by sending infinity to 0 and all other points z to $1/z$.

See also C*, COMPLEX INFINITY, COMPLEX PLANE, EXTENDED COMPLEX PLANE

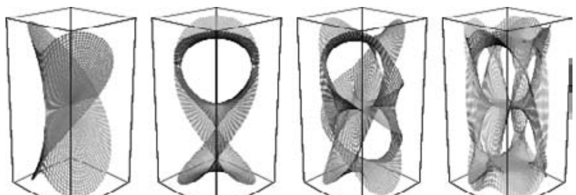
Riemann Sum

Let a CLOSED INTERVAL $[a, b]$ be partitioned by points $a < x_1 < x_2 < \ldots < x_{n-1} < b$, where the lengths of the resulting intervals between the points are denoted $\Delta x_1, \Delta x_2, \ldots, \Delta x_n$. Let x_k^* be an arbitrary point in the kth subinterval. Then the quantity

$$\sum_{k=1}^{n} f(x_k^*)\Delta x_k$$

is called a Riemann sum for a given function $f(x)$ and partition, and the value $\max \Delta x_k$ is called the MESH SIZE of the partition.



If the LIMIT $\max \Delta x_k \to 0$ exists, this limit is known as the Riemann integral of $f(x)$ over the interval $[a, b]$. The shaded areas in the above plots show the LOWER and UPPER SUMS for a constant MESH SIZE.

Riemann Surface

A surface-like configuration which covers the COMPLEX PLANE with several, and in general infinitely many, "sheets." These sheets can have very complicated structures and interconnections (Knopp 1996, pp. 98–99). Riemann surfaces are one way of representing MULTIPLE-VALUED FUNCTIONS; another is BRANCH CUTS. The above plot shows Riemann surfaces for solutions of the equation

$$[w(z)]^d + w(z) + z^{d-1} = 0$$

with $d = 2, 3, 4$, and 5, where $w(z)$ is LAMBERT'S W-FUNCTION (M. Trott).

The Riemann surface S of the FUNCTION FIELD $\mathbf{K}$ is the set of nontrivial discrete valuations on $\mathbf{K}$. Here, the set S corresponds to the IDEALS of the RING A of INTEGERS of $\mathbf{K}$ over $\mathbb{C}(z)$. (A consists of the elements of

K that are ROOTS of MONIC POLYNOMIALS over $\mathbb{C}[z]$.) Riemann surfaces provide a geometric visualization of FUNCTIONS ELEMENTS and their ANALYTIC CONTINUATIONS.

Riemann Tensor

A TENSOR sometimes known as the RIEMANN-CHRISTOFFEL TENSOR. Let

$$\tilde{D}_s \equiv \frac{\partial}{\partial x^s} - \sum_l \left\{ \begin{matrix} s & u \\ & l \end{matrix} \right\}, \tag{1}$$

where the quantity inside the $\left\{ \begin{smallmatrix} s & u \\ & l \end{smallmatrix} \right\}$ is a CHRISTOFFEL SYMBOL OF THE SECOND KIND. Then

$$R_{pqrs} \equiv \tilde{D}_q \left\{ \begin{matrix} p & r \\ & s \end{matrix} \right\} - \tilde{D}_r \left\{ \begin{matrix} r & q \\ & s \end{matrix} \right\}. \tag{2}$$

Broken down into its simplest decomposition in N-D,

$$R_{\lambda\mu\nu\kappa} = \frac{1}{N-2}\left(g_{\lambda\nu}R_{\mu\kappa} - g_{\lambda\kappa}R_{\mu\nu} - g_{\mu\nu}R_{\lambda\kappa} + g_{\mu\kappa}R_{\lambda\nu}\right)$$

$$- \frac{R}{(N-1)(N-2)}\left(g_{\lambda\nu}g_{\mu\kappa} - g_{\lambda\kappa}g_{\mu\nu}\right) + C_{\lambda\mu\nu\kappa}. \tag{3}$$

Here, $R_{\mu\nu}$ is the RICCI TENSOR, R is the CURVATURE SCALAR, and $C_{\lambda\mu\nu\kappa}$ is the WEYL TENSOR.

In terms of the JACOBI TENSOR $J^\mu{}_{\nu\alpha\beta}$,

$$R^\mu{}_{\alpha\nu\beta} = \tfrac{2}{3}\left(J^\mu{}_{\nu\alpha\beta} J^\mu{}_{\beta\alpha\nu}\right). \tag{4}$$

The Riemann tensor is the only tensor that can be constructed from the METRIC TENSOR and its first and second derivatives,

$$R^\alpha{}_{\beta\gamma\delta} = \Gamma^\alpha_{\beta\delta,\,\gamma} - \Gamma^\alpha_{\beta\gamma,\,\delta} + \Gamma^\mu_{\beta\delta}\Gamma^\alpha_{\mu\gamma} - \Gamma^\mu_{\beta\gamma}\Gamma^\alpha_{\mu\delta}, \tag{5}$$

where $\Gamma^\gamma_{\alpha\beta}$ are CONNECTION COEFFICIENTS and $A_{,k}$ is a COMMA DERIVATIVE (Schmutzer 1968, p. 108). In 1-D, $R_{1111} = 0$.

The number of independent coordinates in n-D is given by

$$C_n \equiv \tfrac{1}{12}n^2(n^2-1), \tag{6}$$

the "4-D pyramidal numbers," the first few values of which are 0, 1, 6, 20, 50, 105, 196, 336, 540, 825, ... (Sloane's A002415). The number of SCALARS which can be constructed from $R_{\lambda\mu\nu\kappa}$ and $g_{\mu\nu}$ is

$$S_n \equiv \begin{cases} 1 & \text{for } n=2 \\ \frac{1}{12}\,n(n-1)(n-2)(n+3) & \text{for } n=1,\ n>2 \end{cases} \tag{7}$$

(Weinberg 1972). The first few values are then 0, 1, 3, 14, 40, 90, 175, 308, 504, 780, ... (Sloane's A050297).

Riemann Theta Function

Let the IMAGINARY PART of a $g \times g$ MATRIX F be POSITIVE DEFINITE, and $\mathbf{m} = (m_1, \ldots, m_g)$ be a row VECTOR with coefficients in $\mathbb{Z}$. Then the Riemann theta function is defined by

$$\vartheta(u) = \sum_{\mathbf{m}} \exp\left[2\pi i\left(\mathbf{m}^{\mathrm{T}} u + \tfrac{1}{2}\,\mathbf{m}\mathsf{F}^{\mathrm{T}}\mathbf{m}\right)\right].$$

Riemann Xi Function

XI FUNCTION

Riemann Zeta Function

The Riemann zeta function is an extremely important SPECIAL FUNCTION of mathematics and physics which arises in definite integration and is intimately related with very deep results surrounding the PRIME NUMBER THEOREM. While many of the properties of this function have been investigated, there remain important fundamental conjectures (most notably the RIEMANN HYPOTHESIS) which remain unproved to this day.

On the REAL LINE with $x>1$, the Riemann zeta function can be defined by the integral

$$\zeta(x) \equiv \frac{1}{\Gamma(x)} \int_0^\infty \frac{u^{x-1}}{e^u - 1}\, du, \tag{1}$$

where $\Gamma(n)$ is the GAMMA FUNCTION. If x is an INTEGER n, then we have the identity

$$\frac{u^{n-1}}{e^u - 1} = \frac{e^{-u}u^{n-1}}{1-e^{-u}} = e^{-u}u^{n-1} \sum_{k=0}^\infty e^{-ku} = \sum_{k=1}^\infty e^{-ku}u^{n-1}, \tag{2}$$

so

$$\int_0^\infty \frac{u^{n-1}}{e^u - 1}\, du = \sum_{k=1}^\infty \int_0^\infty e^{-ku}u^{n-1}\, du. \tag{3}$$

To evaluate $\zeta(n)$, let $y \equiv ku$ so that $dy = k\, du$ and plug in the above identity to obtain

$$\begin{aligned}\zeta(n) &= \frac{1}{\Gamma(n)} \sum_{k=1}^\infty \int_0^\infty e^{-ku}u^{n-1}\, du \\ &= \frac{1}{\Gamma(n)} \sum_{k=1}^\infty \int_0^\infty e^{-y}\left(\frac{y}{k}\right)^{n-1} \frac{dy}{k} \\ &= \frac{1}{\Gamma(n)} \sum_{k=1}^\infty \frac{1}{k^n} \int_0^\infty e^{-y}y^{n-1}\, dy.\end{aligned} \tag{4}$$

Integrating the final expression in (4) gives $\Gamma(n)$, which cancels the factor $1/\Gamma(n)$ and gives the most common form of the Riemann zeta function,

$$\zeta(n) = \sum_{k=1}^\infty \frac{1}{k^n}. \tag{5}$$

The Riemann zeta function can also be defined in terms of MULTIPLE INTEGRALS by

$$\zeta(n) = \underbrace{\int_0^1 \cdots \int_0^1}_{n} \frac{\prod_{i=1}^n dx_i}{1 - \prod_{i=1}^n x_i}, \tag{6}$$

and as a MELLIN TRANSFORM by

$$\int_0^\infty \operatorname{frac}\left(\frac{1}{t}\right) t^{n-1}\, dt = -\frac{\zeta(s)}{s} \tag{7}$$

for $0 < \Re[s] < 1$, where frac(x) is the FRACTIONAL PART (Balazard and Saias 2000).

Note that the zeta function has a singularity at $n=1$, where it reduces to the divergent HARMONIC SERIES.

The Riemann zeta function satisfies the functional equation

$$\zeta(1-s) = 2(2\pi)^{-s} \cos\left(\tfrac{1}{2}s\pi\right)\Gamma(s)\zeta(s) \tag{8}$$

(Hardy 1999, p. 14; Krantz 1999, p. 160).

As defined above, the zeta function $\zeta(s)$ with $s = \sigma + it$ a COMPLEX NUMBER is defined for $\Re[s] > 1$. However, $\zeta(s)$ has a unique ANALYTIC CONTINUATION to the entire COMPLEX PLANE, excluding the point $s=1$, which corresponds to a SIMPLE POLE with RESIDUE 1 (Krantz 1999, p. 160). In particular, as $s \to 1$, $\zeta(s)$ obeys

$$\lim_{s\to 1} \zeta(s) - \frac{1}{s-1} = \gamma, \tag{9}$$

where γ is the EULER-MASCHERONI CONSTANT (Whittaker and Watson 1990, p. 271).

To perform the ANALYTIC CONTINUATION for $\Re[s] > 0$, write

$$\sum_{n=1}^\infty (-1)^n n^{-s} + \sum_{n=1}^\infty n^{-s} = 2 \sum_{n=2,\,4,\,\ldots}^\infty n^{-s}$$

$$= 2\sum_{k=1}^{\infty}(2k)^{-s} = 2^{1-s}\sum_{n=1}^{\infty}k^{-s} \quad (10)$$

$$\sum_{n=1}^{\infty}(-1)^n n^{-s} + \zeta(s) = 2^{1-s}\zeta(s). \quad (11)$$

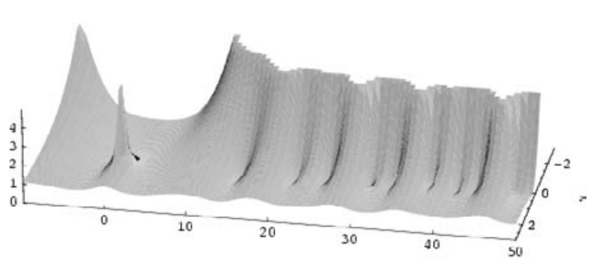
Therefore,

$$\zeta(s) = \frac{1}{1-2^{1-s}}\sum_{n=1}^{\infty}(-1)^{n-1}n^{-s}. \quad (12)$$

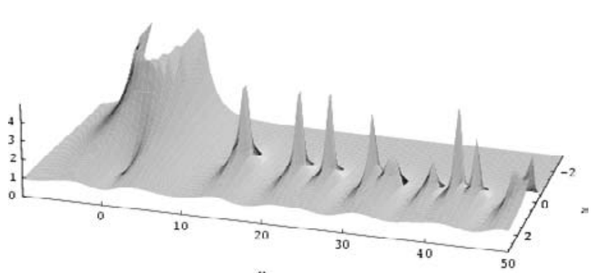
While this form defines $\zeta(s)$ for only the UPPER HALF-PLANE $\Re[s] > 0$, equation (8) can be used to analytically continue it to the rest of the COMPLEX PLANE. Analytic continuation can also be performed using HANKEL FUNCTIONS. A globally convergent series for the Riemann zeta function is given by

$$\zeta(z) = \frac{1}{1-2^{1-z}}\sum_{n=0}^{\infty}\frac{1}{2^{n+1}}\sum_{k=0}^{n}(-1)^k\binom{n}{k}(k+1)^{-z}, \quad (13)$$

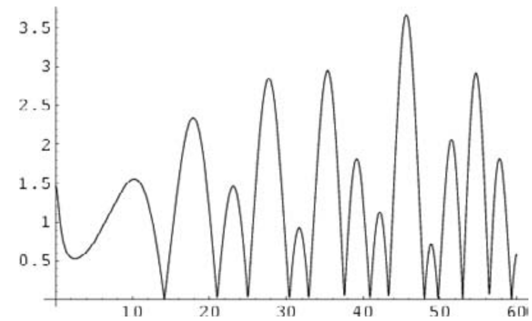
where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.



A generalized Riemann zeta function $\zeta(s, a)$ known as the HURWITZ ZETA FUNCTION can also be defined such that



$$\zeta(s) \equiv \zeta(s, 0). \quad (14)$$



In the COMPLEX PLANE, trivial zeros of $\zeta(s)$ occur at $s = -2, -4, -6, \ldots$, and nontrivial zeros at

$$s \equiv \sigma + it \quad (15)$$

for $0 \le \sigma \le 1$. The figures below show the structure of the complex $\zeta(z)$ by plotting $|\zeta(z)|$ and $1/|\zeta(z)|$.

The RIEMANN HYPOTHESIS asserts that the nontrivial ROOTS of $\zeta(s)$ all have REAL PART $\sigma = \Re[s] = 1/2$, a line called the "CRITICAL LINE." This is known to be true for the first 200, 000, 001 roots (Brent *et al.* 1982). The above plot shows $|\zeta(1/2 + it)|$ for t between 0 and 60. As can be seen, the first few nontrivial zeros occur at $t = 14.134725$, 21.022040, 25.010858, 30.424876, 32.935062, 37.586178, ... (Wagon 1991, pp. 361–362 and 367–368; Odlyzko). Wiener showed that the PRIME NUMBER THEOREM is literally equivalent to the assertion that $\zeta(s)$ has no zeros on $\sigma = 1$ (Hardy 1999, p. 34).

The Riemann zeta function can be factored over its nontrivial zeros ρ as

$$\zeta(s) = \frac{e^{\ln(2\pi)-1-\gamma/2)_s}}{2(s-1)\Gamma\left(1+\frac{1}{2}s\right)}\prod_{\rho}\left(1-\frac{s}{\rho}\right)e^{s/\rho} \quad (16)$$

(Voros 1987).

The Riemann zeta function can be split up into

$$\zeta\left(\tfrac{1}{2}+it\right) = z(t)e^{-i\vartheta(t)}, \quad (17)$$

where $z(t)$ and $\vartheta(t)$ are the RIEMANN-SIEGEL FUNCTIONS. The Riemann zeta function is related to the DIRICHLET LAMBDA FUNCTION $\lambda(\nu)$ and DIRICHLET ETA FUNCTION $\eta(\nu)$ by

$$\frac{\zeta(\nu)}{2^\nu} = \frac{\lambda(\nu)}{2^\nu - 1} = \frac{\eta(\nu)}{2^\nu - 2} \quad (18)$$

and

$$\zeta(\nu) + \eta(\nu) = 2\lambda(\nu) \quad (19)$$

(Spanier and Oldham 1987). It is related to the LIOUVILLE FUNCTION $\lambda(v)$ by

$$\frac{\zeta(2s)}{\zeta(s)} = \sum_{n=1}^{\infty}\frac{\lambda(n)}{n^s} \quad (20)$$

(Lehman 1960, Hardy and Wright 1979). Furthermore,

$$\frac{\zeta^2(s)}{\zeta(2s)} = \sum_{n=1}^{\infty}\frac{2^{\omega(n)}}{n^s}, \quad (21)$$

where $\omega(n)$ is the number of DISTINCT PRIME FACTORS of n (Hardy and Wright 1979, p. 254).

Two sum identities involving $\zeta(n)$ are

$$\sum_{n=2}^{\infty}[\zeta(n)-1]=1 \tag{22}$$

$$\sum_{n=2}^{\infty}(-1)^n[\zeta(n)-1]=\tfrac{1}{2}. \tag{23}$$

The Riemann zeta function is related to the GAMMA FUNCTION $\Gamma(z)$ by

$$\Gamma\left(\frac{s}{2}\right)\pi^{-s/2}\zeta(s)=\Gamma\left(\frac{1-s}{2}\right)\pi^{-(1-s)/2}\zeta(1-s). \tag{24}$$

The DERIVATIVE of the Riemann zeta function is defined by

$$\zeta'(s)=-s\sum_{k=1}^{\infty}k^{-s}\ln k=-\sum_{k=2}^{\infty}\frac{\ln k}{k^s}. \tag{25}$$

As $s \to 0$,

$$\zeta'(0)=-\tfrac{1}{2}\ln(2\pi). \tag{26}$$

$\zeta(n)$ is known to be transcendental for all EVEN n, but the study of the function at ODD n is significantly more difficult. Apéry (1979) finally proved that $\zeta(3)$ to be IRRATIONAL, but no similar results are known for other ODD n. However, Rivoal (2000) recently proved that there are infinitely many integers n such that $\zeta(2n+1)$ is irrational. As a result of Apéry's important discovery, $\zeta(3)$ is sometimes called APÉRY'S CONSTANT. A number of interesting sums for $\zeta(n)$, with n a POSITIVE INTEGER, can be written in terms of binomial coefficients as the BINOMIAL SUMS

$$\zeta(2)=3\sum_{k=1}^{\infty}\frac{1}{k^2\binom{2k}{k}} \tag{27}$$

$$\zeta(3)=\frac{5}{2}\sum_{k=1}^{\infty}\frac{(-1)^{k-1}}{k^3\binom{2k}{k}} \tag{28}$$

$$\zeta(4)=\frac{36}{17}\sum_{k=1}^{\infty}\frac{1}{k^4\binom{2k}{k}} \tag{29}$$

(Guy 1994, p. 257). Apéry arrived at his result with the aid of the k^{-3} sum formula above. A relation OF THE FORM

$$\zeta(5)=Z_5\sum_{k=1}^{\infty}\frac{(-1)^{k-1}}{k^5\binom{2k}{k}} \tag{30}$$

has been searched for with Z_5 a RATIONAL or ALGEBRAIC NUMBER, but if Z_5 is a ROOT of a POLYNOMIAL of degree 25 or less, then the Euclidean norm of the coefficients must be larger than 2×10^{37} (Bailey and Plouffe). Therefore, no such sums for $\zeta(n)$ are known for $n \geq 5$.

The Riemann zeta function may be computed analytically for EVEN n using either CONTOUR INTEGRATION or PARSEVAL'S THEOREM with the appropriate FOURIER SERIES. An unexpected and important formula involving the product of PRIMES was first discovered by Euler in 1737,

$$\begin{aligned}\zeta(x)(1-2^{-x})&=\left(1+\frac{1}{2^x}+\frac{1}{3^x}+\ldots\right)\left(1-\frac{1}{2^x}\right)\\&=\left(1+\frac{1}{2^x}+\frac{1}{3^x}+\ldots\right)-\left(\frac{1}{2^x}+\frac{1}{4^x}+\frac{1}{6^x}+\ldots\right)\end{aligned} \tag{31}$$

$$\begin{aligned}&\zeta(x)(1-2^{-x})(1-3^{-x})\\&=\left(1+\frac{1}{3^x}+\frac{1}{5^x}+\frac{1}{7^x}+\ldots\right)-\left(\frac{1}{3^x}+\frac{1}{9^x}+\frac{1}{15^x}+\ldots\right)\end{aligned} \tag{32}$$

$$\begin{aligned}&\zeta(x)(1-2^{-x})(1-3^{-x})\cdots(1-p^{-z})\cdots\\&=\zeta(x)\prod_{n=2}^{\infty}(1-p^{-x})=1.\end{aligned} \tag{33}$$

Here, each subsequent multiplication by the next PRIME p leaves only terms which are POWERS of p^{-x}. Therefore,

$$\zeta(x)=\left[\prod_{p=2}^{\infty}(1-p^{-x})\right]^{-1}, \tag{34}$$

where p runs over all PRIMES (Hardy 1999, p. 18; Krantz 1999, p. 159). Euler's product formula can also be written

$$\zeta(s)=(1-2^{-s})^{-1}\prod_{\substack{q=1\\(\text{mod }4)}}(1-q^{-s})^{-1}\prod_{\substack{r=3\\(\text{mod }4)}}(1-r^{-s})^{-1}. \tag{35}$$

For EVEN $n \equiv 2k$,

$$\zeta(n)=\frac{2^{n-1}|B_n|\pi^n}{n!}, \tag{36}$$

where B_n is a BERNOULLI NUMBER. Another intimate connection with the BERNOULLI NUMBERS is provided by

$$B_n=(-1)^{n+1}n\zeta(1-n) \tag{37}$$

for $n \geq 1$, which can be written

$$B_n = -n\zeta(1-n) \quad (38)$$

for $n \geq 2$. Although no analytic form for $\zeta(n)$ is known for ODD n,

$$\zeta(3) = \frac{1}{2}\sum_{k=1}^{\infty}\frac{1}{k^2}\left(1+\frac{1}{2}+\ldots+\frac{1}{k}\right) = \frac{1}{2}\sum_{k=1}^{\infty}\frac{h_k}{k^2}, \quad (39)$$

where h_k is a HARMONIC NUMBER (Stark 1974). In addition, $\zeta(n)$ can be expressed as the sum limit

$$\zeta(n) = \lim_{x\to\infty}\frac{1}{(2x+1)^n}\sum_{k=1}^{x}\left[\cot\left(\frac{k}{2x+1}\right)\right]^n \quad (40)$$

for $n = 3, 5, \ldots$ (Apostol 1973, given incorrectly in Stark 1974).

For $\mu(n)$ the MÖBIUS FUNCTION,

$$\frac{1}{\zeta(s)} = \sum_{n=1}^{\infty}\frac{\mu(n)}{n^s}. \quad (41)$$

The values for small integral arguments are

$$\zeta(1) = \infty$$

$$\zeta(2) = \frac{\pi^2}{6}$$

$$\zeta(3) = 1.2020569032\ldots$$

$$\zeta(4) = \frac{\pi^4}{90}$$

$$\zeta(5) = 1.0369277551\ldots$$

$$\zeta(6) = \frac{\pi^6}{945}$$

$$\zeta(7) = 1.0083492774\ldots$$

$$\zeta(8) = \frac{\pi^8}{9450}$$

$$\zeta(9) = 1.0020083928\ldots$$

$$\zeta(10) = \frac{\pi^{10}}{93,555}.$$

Euler gave $\zeta(2)$ to $\zeta(26)$ for EVEN n (Wells 1986, p. 54), and Stieltjes (1993) determined the values of $\zeta(2)$, ..., $\zeta(70)$ to 30 digits of accuracy in 1887. The denominators of $\zeta(2n)$ for $n = 1, 2, \ldots$ are 6, 90, 945, 9450, 93555, 638512875, ... (Sloane's A002432).

The value at $n = 0$ is given by

$$\zeta(0) = -\tfrac{1}{2} \quad (42)$$

The value $\zeta(-1) = -1/12$ is a deep result of renormalization theory (Elizalde *et al.* 1994, Elizalde 1995). In general,

$$\zeta(-n) = -\frac{B_{n+1}}{n+1} \quad (43)$$

for $n = 1, 3, \ldots$ where B_n is a BERNOULLI NUMBER, the first few values of which are $-1/12$, $1/120$, $-1/252$, $1/240$, ... (Sloane's A001067 and A006953).

Rapidly converging series for $\zeta(n)$ for n odd were first discovered by Ramanujan (Zucker 1979, Zucker 1984, Berndt 1988, Bailey *et al.* 1997, Cohen 2000). For $n > 1$ and $n \equiv 3 \pmod 4$,

$$\zeta(n) = \frac{2^{n-1}\pi^n}{(n+1)!}\sum_{k=0}^{(n+1)/2}(-1)^{k-1}\binom{n+1}{2k}B_{n+1-2k}B_{2k} - 2\sum_{k=1}^{\infty}\frac{1}{k^n(e^{2\pi k}-1)}, \quad (44)$$

where B_k is again a BERNOULLI NUMBER and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The first few for $n = 3, 7, 11, \ldots$ are 7/180, 19/56700, 1453/425675250, 13687/390769879500, 7708537/21438612514068750, ... (Sloane's A057866 and A057867). For $n \geq 5$ and $n \equiv 1 \pmod 4$, the corresponding formula is slightly messier,

$$\zeta(n) = \frac{(2\pi)^n}{(n+1)!(n-1)} \times \sum_{k=0}^{(n+1)/4}(-1)^k(n+1-4k)\binom{n+1}{2k}B_{n+1-2k}B_{2k} - 2\sum_{k=1}^{\infty}\frac{e^{2\pi k}\left(1+\frac{4\pi k}{k-1}\right)-1}{k^n(e^{2\pi k}-1)^2}. \quad (45)$$

Defining

$$S_{\pm}(n) \equiv \sum_{k=1}^{\infty}\frac{1}{k^n(e^{2\pi k}\pm 1)}, \quad (46)$$

the first few values can then be written

$$\zeta(3) = \tfrac{7}{180}\pi^3 - 2S_-(3) \quad (47)$$

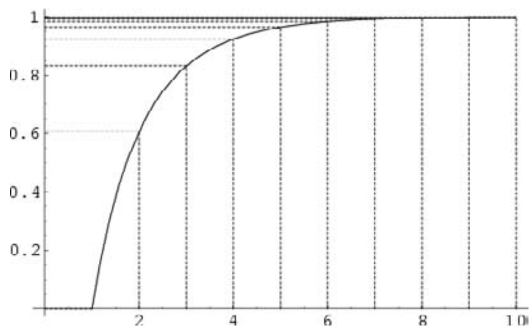
$$\zeta(5) = \tfrac{1}{294}\pi^5 - \tfrac{72}{35}S_-(5) - \tfrac{2}{35}S_+(5) \quad (48)$$

$$\zeta(7) = \tfrac{19}{56700}\pi^7 - 2S_-(7) \quad (49)$$

$$\zeta(9) = \tfrac{125}{3704778}\pi^9 - \tfrac{992}{495}S_-(9) - \tfrac{2}{495}S_+(9) \quad (50)$$

$$\zeta(11) = \tfrac{1453}{425675250}\pi^{11} - 2S_-(11) \quad (51)$$

$$\zeta(13) = \tfrac{89}{257432175}\pi^{13} - \tfrac{16512}{8255}S_-(13) - \tfrac{2}{8255}S_+(13) \quad (52)$$



$$\zeta(15) = \tfrac{13687}{390769879500}\pi^{15} - 2S_-(15) \quad (53)$$

$$\zeta(17) = \tfrac{397549}{112024529867250}\pi^{17} - \tfrac{261632}{130815}S_-(17) - \tfrac{2}{130815}S_+(17) \quad (54)$$

$$\zeta(19) = \tfrac{7708537}{21438612514068750}\pi^{19} - 2S_{-}(19) \qquad (55)$$

$$\zeta(21) = \tfrac{68529640373}{1881063815762259253125}\pi^{21} - \tfrac{4196352}{2098175}S_{-}(21) - \tfrac{2}{2098175}S_{+}(21) \qquad (56)$$

(Plouffe).

The inverse of the RIEMANN ZETA FUNCTION $1/\zeta(p)$, plotted above, is the asymptotic density of p th-powerfree numbers (i.e., SQUAREFREE numbers, CUBEFREE numbers, etc.). The following table gives the number $Q_p(n)$ of p th-powerfree numbers $\leq n$ for several values of n.

p	$1/\zeta(p)$	$Q_p(10)$	$Q_p(100)$	$Q_p(10^3)$	$Q_p(10^4)$	$Q_p(10^5)$	$Q_p(10^6)$

Riemann Zeta Function Zeta(2)

The value for $\zeta(2)$ can be found using a number of different techniques (Apostol 1983, Choe 1987, Giesy 1972, Holme 1970, Kimble 1987, Knopp and Schur 1918, Kortram 1996, Matsuoka 1961, Papadimitriou 1973, Simmons 1992, Stark 1969, Stark 1970, Yaglom and Yaglom 1987). The problem of finding this value analytically is sometimes known as the BASLER PROBLEM (Castellanos 1988). Yaglom and Yaglom (1987), Holme (1970), and Papadimitriou (1973) all derive the result, $\pi^2/6$ from DE MOIVRE'S IDENTITY or related identities.

One derivation for $\zeta(2)$ considers the FOURIER SERIES of $f(x)=x^{2n}$

$$f(x)=\tfrac{1}{2}a_0+\sum_{m=1}^{\infty}a_m\cos(mx)+\sum_{m=1}^{\infty}b_m\sin(mx),\qquad(1)$$

which has coefficients given by

$$a_0=\frac{1}{\pi}\int_{-\pi}^{\pi}f(x)\,dx=\frac{2}{\pi}\int_0^{\pi}x^{2n}\,dx=\frac{2}{\pi}\left[\frac{x^{2n+1}}{2n+1}\right]_0^{\pi}=\frac{2\pi^{2n}}{2n+1}\qquad(2)$$

$$a_m=\frac{1}{\pi}\int_{-\pi}^{\pi}x^{2n}\cos(mx)\,dx=\frac{2}{\pi}\int_0^{\pi}x^{2n}\cos(mx)\,dx\qquad(3)$$

$$b_m=\frac{1}{\pi}\int_{-\pi}^{\pi}x^{2n}\sin(mx)\,dx=0,\qquad(4)$$

where the latter is true since the integrand is ODD. Therefore, the FOURIER SERIES is given explicitly by

$$x^{2n}=\frac{\pi^{2n}}{2n+1}+\sum_{m=1}^{\infty}a_m\cos(mx).\qquad(5)$$

Now, a_m is given by the COSINE INTEGRAL

$$a_m=\frac{2}{\pi}(-1)^{n+1}(2n)!\left[\sin(mx)\sum_{k=0}^{n}\frac{(-1)^k}{(2k)!m^{2n-2k+1}}x^{2k}+\cos(mx)\sum_{k=1}^{n}\frac{(-1)^{k+1}}{(2k-3)!m^{2n-2k+2}}x^{2k-1}\right]_0^{\pi}.\qquad(6)$$

But $\cos(m\pi)=(-1)^m$, and $\sin(m\pi)=\sin 0=0$, so

$$a_m=\frac{2}{\pi}(-1)^{n+1}(2n)!(-1)^m\sum_{k=1}^{n}\frac{(-1)^{k+1}}{(2k-3)!m^{2n-2k+2}}\pi^{2k-1}$$

$$= (-1)^{m+n} 2(2n)! \sum_{k=1}^{n} \frac{(-1)^k}{(2k-3)! m^{2n-2k+2}} \pi^{2k-2}. \quad (7)$$

Now, if $n = 1$,

$$a_m = (-1)^{m+1} 2(2!) \sum_{k=1}^{1} \frac{(-1)^k}{(2k-3)! m^{4-2k}} \pi^{2k-2}$$

$$= 4(-1)^{m+1} \frac{(-1)}{(-1)! m^2} \pi^0 = \frac{4(-1)^m}{m^2}, \quad (8)$$

so the FOURIER SERIES is

$$x^2 = \frac{\pi^2}{3} + 4 \sum_{m=1}^{\infty} \frac{(-1)^m \cos(mx)}{m^2}. \quad (9)$$

Letting $m \equiv \pi$ gives $\cos(m\pi) = (-1)^m$, so

$$\pi^2 = \frac{\pi^2}{3} + 4 \sum_{m=1}^{\infty} \frac{1}{m^2}, \quad (10)$$

and we have

$$\zeta(2) = \sum_{m=1}^{\infty} \frac{1}{m^2} = \frac{\pi^2}{6}. \quad (11)$$

Higher values of n can be obtained by finding a_m and proceeding as above.

The value $\zeta(2)$ can also be found simply using the ROOT LINEAR COEFFICIENT THEOREM. Consider the equation $\sin z = 0$ and expand sin in a MACLAURIN SERIES

$$\sin z = z - \frac{z^3}{3!} + \frac{z^5}{5!} + \ldots = 0 \quad (12)$$

$$0 = 1 - \frac{z^2}{3!} + \frac{z^4}{5!} + \ldots = 1 - \frac{w}{3!} + \frac{w^2}{5!} + \ldots, \quad (13)$$

where $w \equiv z^2$. But the zeros of $\sin(z)$ occur at π, 2π, 3π, ..., so the zeros of $\sin w = \sin\sqrt{z}$ occur at π^2, $(2\pi)^2$, ... Therefore, the sum of the roots equals the COEFFICIENT of the leading term

$$\frac{1}{\pi^2} + \frac{1}{(2\pi)^2} + \frac{1}{(3\pi)^2} + \ldots = \frac{1}{3!} = \frac{1}{6}, \quad (14)$$

which can be rearranged to yield

$$\zeta(2) = \frac{\pi^2}{6}. \quad (15)$$

Yet another derivation (Simmons 1992) evaluates the integral using the integral

$$I = \int_0^1 \int_0^1 \frac{dx\,dy}{1 - xy} = \int_0^1 \int_0^1 (1 + xy + x^2y^2 + \ldots)\,dx\,dy$$

$$= \int_0^1 [(x + \tfrac{1}{2}x^2y + \tfrac{1}{3}x^3y^2 + \ldots)]_0^1\,dy$$

$$= \int_0^1 (1 + \tfrac{1}{2}y + \tfrac{1}{3}y^2 + \ldots)\,dy$$

$$= \left[y + \frac{y^2}{2^2} + \frac{y^3}{3^2} + \ldots\right]_0^1 = 1 + \frac{1}{2^2} + \frac{1}{3^2} + \ldots. \quad (16)$$

To evaluate the integral, rotate the coordinate system by $\pi/4$ so

$$x = u\cos\theta - v\sin\theta = \tfrac{1}{2}\sqrt{2}(u - v) \quad (17)$$

$$y = u\sin\theta + v\cos\theta = \tfrac{1}{2}\sqrt{2}(u + v) \quad (18)$$

and

$$xy = \tfrac{1}{2}(u^2 - v^2) \quad (19)$$

$$1 - xy = \tfrac{1}{2}(2 - u^2 + v^2). \quad (20)$$

Then

$$I = 4\int_0^{\sqrt{2}/2} \int_0^u \frac{du\,dv}{2 - u^2 + v^2} + 4\int_{\sqrt{2}/2}^{\sqrt{2}} \int_0^{\sqrt{2}-u} \frac{du\,dv}{2 - u^2 + v^2} \equiv I_1 + I_2. \quad (21)$$

Now compute the integrals I_1 and I_2.

$$I_1 = 4\int_0^{\sqrt{2}/2} \left[\int_0^u \frac{dv}{2 - u^2 + v^2}\right] du$$

$$= 4\int_0^{\sqrt{2}/2} \left[\frac{1}{\sqrt{2 - u^2}} \tan^{-1}\left(\frac{v}{\sqrt{2 - u^2}}\right)\right]_0^u du$$

$$= 4\int_0^{\sqrt{2}/2} \frac{1}{\sqrt{2 - u^2}} \tan^{-1}\left(\frac{u}{\sqrt{2 - u^2}}\right) du. \quad (22)$$

Make the substitution

$$u = \sqrt{2}\sin\theta \quad (23)$$

$$\sqrt{2 - u^2} = \sqrt{2}\cos\theta \quad (24)$$

$$du = \sqrt{2}\cos\theta\,d\theta, \quad (25)$$

so

$$\tan^{-1}\left(\frac{u}{\sqrt{2 - u^2}}\right) = \tan^{-1}\left(\frac{\sqrt{2}\sin\theta}{\sqrt{2}\cos\theta}\right) = \theta \quad (26)$$

and

$$I_1 = 4\int_0^{\pi/6} \frac{1}{\sqrt{2}\cos\theta} \theta\sqrt{2}\cos\theta\,d\theta = 2[\theta^2]_0^{\pi/6}$$

$$= \frac{\pi^2}{18}. \quad (27)$$

I_2 can also be computed analytically,

$$I_2 = 4\int_{\sqrt{2}/2}^{\sqrt{2}} \left[\int_0^{\sqrt{2}-u} \frac{dv}{2-u^2+v^2}\right] du$$

$$= 4\int_{\sqrt{2}/2}^{\sqrt{2}} \left[\frac{1}{\sqrt{2-u^2}} \tan^{-1}\left(\frac{v}{\sqrt{2-u^2}}\right)\right]_0^{\sqrt{2}-u} du$$

$$= 4\int_{\sqrt{2}/2}^{\sqrt{2}} \frac{1}{\sqrt{2-u^2}} \tan^{-1}\left(\frac{\sqrt{2}-u}{\sqrt{2-u^2}}\right) du. \tag{28}$$

But

$$\tan^{-1}\left(\frac{\sqrt{2}-u}{\sqrt{2-u^2}}\right) = \tan^{-1}\left(\frac{\sqrt{2}-\sqrt{2}\sin\theta}{\sqrt{2}\cos\theta}\right)$$

$$= \tan\left(\frac{1-\sin\theta}{\cos\theta}\right) = \tan^{-1}\left(\frac{\cos\theta}{1+\sin\theta}\right)$$

$$= \tan^{-1}\left[\frac{\sin\left(\frac{1}{2}\pi-\theta\right)}{1+\cos\left(\frac{1}{2}\pi-\theta\right)}\right]$$

$$= \tan^{-1}\left\{\frac{2\sin\left[\frac{1}{2}\left(\frac{1}{2}\pi-\theta\right)\right]\cos\left[\frac{1}{2}\left(\frac{1}{2}\pi-\theta\right)\right]}{2\cos^2\left[\frac{1}{2}\left(\frac{1}{2}\pi-\theta\right)\right]}\right\}$$

$$= \tfrac{1}{2}\left(\tfrac{1}{2}\pi-\theta\right), \tag{29}$$

so

$$I_2 = 4\int_{\pi/6}^{\pi/2} \frac{1}{\sqrt{2}\cos\theta}\left(\tfrac{1}{4}\pi-\tfrac{1}{2}\theta\right)\sqrt{2}\cos\theta\, d\theta$$

$$= 4\left[\tfrac{1}{4}\pi\theta-\tfrac{1}{4}\theta^2\right]_{\pi/6}^{\pi/2}$$

$$= 4\left[\left(\frac{\pi^2}{8}-\frac{\pi^2}{16}\right)-\left(\frac{\pi^2}{24}-\frac{\pi^2}{144}\right)\right] = \frac{\pi^2}{9}. \tag{30}$$

Combining I_1 and I_2 gives

$$\zeta(2) = I_1 + I_2 = \frac{\pi^2}{18}+\frac{\pi^2}{9} = \frac{\pi^2}{6}. \tag{31}$$

Riemannian Geometry

The study of MANIFOLDS having a complete RIEMANNIAN METRIC. Riemannian geometry is a general space based on the LINE ELEMENT

$$ds = F(x^1, \ldots, x^n;\, dx^1, \ldots, dx^n),$$

with $F(x, y) > 0$ for $y \neq 0$ a function on the TANGENT BUNDLE TM. In addition, F is homogeneous of degree 1 in y and OF THE FORM

$$F^2 = g_{ij}(x)\, dx^i\, dx^j$$

(Chern 1996). If this restriction is dropped, the resulting geometry is called FINSLER GEOMETRY.

Riemannian Geometry (Non-Euclidean)

ELLIPTIC GEOMETRY

Riemannian Manifold

A MANIFOLD possessing a METRIC TENSOR. For a complete Riemannian manifold, the METRIC $d(x, y)$ is defined as the length of the shortest curve (GEODESIC) between x and y.

See also BISHOP'S INEQUALITY, CAMPBELL'S THEOREM, CHEEGER'S FINITENESS THEOREM, PSEUDO-RIEMANNIAN MANIFOLD

Riemannian Metric

Suppose for every point x in a COMPACT MANIFOLD M, an INNER PRODUCT $\langle \cdot, \cdot \rangle_x$ is defined on a TANGENT SPACE T_xM of M at x. Then the collection of all these INNER PRODUCTS is called the Riemannian metric. In 1870, Christoffel and Lipschitz showed how to decide when two Riemannian metrics differ by only a coordinate transformation.

See also COMPACT MANIFOLD, LINE ELEMENT, METRIC TENSOR

Riemannian Submersion

See also SUBMERSION

Riemann-Lebesgue Lemma

Sometimes also called MERCER'S THEOREM.

$$\lim_{n\to\infty} \int_a^b K(\lambda, z) C \sin(nz)\, dz = 0$$

for arbitrarily large C and "nice" $K(\lambda, z)$. Gradshteyn and Ryzhik (2000) state the lemma as follows. If $f(x)$ is integrable on $[-\pi, \pi]$, then

$$\lim_{t\to\infty} \int_{-\pi}^{\pi} f(x) \sin(tx)\, dx \to 0$$

and

$$\lim_{t\to\infty} \int_{-\pi}^{\pi} f(x) \cos(tx)\, dx \to 0.$$

Riemann's Integral Theorem

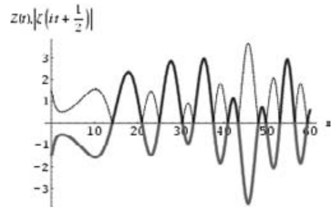
Associated with an irreducible curve of GENUS (CURVE) p, there are p LINEARLY INDEPENDENT integrals of the first sort. The ROOTS of the integrands are groups of the canonical series, and every such group will give rise to exactly one integral of the first sort.

References

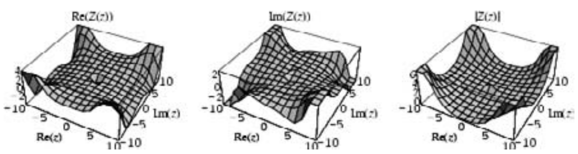
Coolidge, J. L. *A Treatise on Algebraic Plane Curves.* New York: Dover, p. 274, 1959.

Riemann's Moduli Problem

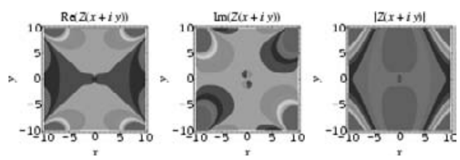
Find an ANALYTIC parameterization of the compact RIEMANN SURFACES in a fixed HOMOMORPHISM class. The AHLFORS-BERS THEOREM proved that RIEMANN'S MODULI SPACE gives the solution.



See also AHLFORS-BERS THEOREM, RIEMANN'S MODULI SPACE



Riemann's Moduli Space



Riemann's moduli space R_p is the space of ANALYTIC EQUIVALENCE CLASSES of RIEMANN SURFACES of fixed GENUS p.

See also AHLFORS-BERS THEOREM, RIEMANN'S MODULI PROBLEM, RIEMANN SURFACE

Riemann-Siegel Functions

For a REAL POSITIVE t, the Riemann-Siegel Z function is defined by

$$Z(t) \equiv e^{i\theta}(t)\zeta(\tfrac{1}{2}+it).$$

This function is sometimes also called the Hardy function or Hardy Z-function (Karatsuba and Voronin 1992, Borwein *et al.* 1999). The top plot superposes $Z(t)$ (thick line) on $\left|\zeta\left(\frac{1}{2}+it\right)\right|$, where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. It has an ASYMPTOTIC SERIES given "approximately" by

$$Z(t) \sim 2\sum_{k=1}^{\nu(t)} \frac{1}{\sqrt{k}} \cos[\vartheta(t) - t\ln k] + R(t), \tag{1}$$

where

$$\nu(t) = \left\lfloor \sqrt{\frac{t}{2\pi}} \right\rfloor \tag{2}$$

$$R(t) = (-1)^{\nu(t)-1}\left(\frac{t}{2\pi}\right)^{-1/4}$$

$$\times \sum_{k=0}^{\infty} c_k\left(\sqrt{\frac{t}{2\pi}} - \nu(t)\right)\left(\frac{t}{2\pi}\right)^{-k/2} \tag{3}$$

$$c_k(p) = \left[\omega^k\right]\left\{\exp\left[i\left(\ln\left(\frac{t}{2\pi}\right) - \tfrac{1}{2}t - \tfrac{1}{8}\pi - \vartheta(t)\right)\right]\right.$$

$$\left.\times\left[y^0\right]\left[\left(\sum_{j=0}^{\infty} A_j(y)\omega^j\right)\left(\sum_{j=0}^{\infty}\frac{\psi^{(j)}(p)}{j!}y^j\right)\right]\right\} \tag{4}$$

$$A_0(y) = e^{2\pi i y^2} \tag{5}$$

$$A_j(y) = -\tfrac{1}{2}yA_{j-1}(y) - \frac{1}{32\pi^2}\frac{\partial^2}{\partial y^2}\frac{A_{j-1}(y)}{y} \tag{6}$$

$$\psi(p) = \frac{\cos[2\pi(p^2 - p - \frac{1}{16})]}{\cos(2\pi p)} \tag{7}$$

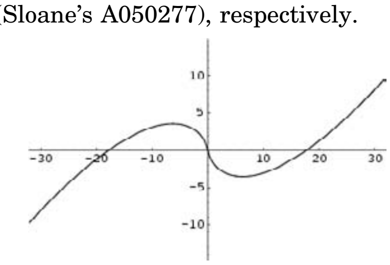
$\lfloor x \rfloor$ is the FLOOR FUNCTION (Edwards 1974), and $\left[y^k\right]$ is COEFFICIENT NOTATION. The first few terms $c_k(p)$ are given by

$$c_0(p) = \psi(p) \tag{8}$$

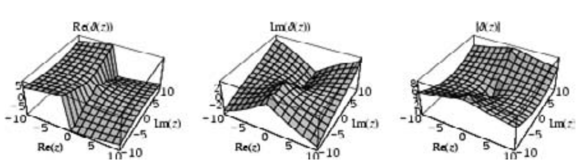
$$c_1(p) = -\frac{\psi^{(3)}(p)}{96\pi^2} \tag{9}$$

$$c_2(p) = \frac{\psi''(p)}{64\pi^2} + \frac{\psi^{(6)}(p)}{18432\pi^4} \tag{10}$$

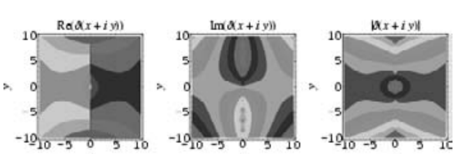
$$c_3(p) = \frac{\psi'(p)}{64\pi^2} + \frac{\psi^{(5)}(p)}{3840\pi^4} - \frac{\psi^{(9)}(p)}{5308416\pi^6} \tag{11}$$



$$c_4(p) = \frac{\psi(p)}{128\pi^2} + \frac{19\psi^{(4)}(p)}{24576\pi^4} + \frac{11\psi^{(8)}(p)}{5898240\pi^6}$$



$$+\frac{\psi^{(12)}(p)}{2038431744\pi^8} \tag{12}$$



$$c_5(p) = -\frac{5\psi^{(3)}(p)}{3072\pi^4} - \frac{901\psi^{(7)}(p)}{82575360\pi^6}$$

$$-\frac{7\psi^{(11)}(p)}{849346560\pi^8} - \frac{\psi^{(15)}(p)}{978447237120\pi^{10}}. \tag{13}$$

The numerators and denominators are 1, -1, 1, 1, -1, -1, -1, 1, 19, 11, 1, -5, -901, ... (Sloane's A050276) and 1, 96, 64, 18432, 64, 3840, 5308416, 128, ... (Sloane's A050277), respectively.

The Riemann-Siegel theta function appearing above is defined by

$$\vartheta(t) \equiv \Im\left[\ln \Gamma\left(\tfrac{1}{4}+\tfrac{1}{2}it\right) - \tfrac{1}{2}t \ln \pi\right]$$
$$= \arg\left[\Gamma\left(\tfrac{1}{4}+\tfrac{1}{2}it\right)\right] - \tfrac{1}{2}t \ln \pi.$$

These functions are implemented in *Mathematica* as `RiemannSiegelZ[z]` and `RiemannSiegelTheta[z]`, illustrated above.

Riesel Number

There exist infinitely many odd integers k such that $k \cdot 2^n - 1$ is composite for every $n \geq 1$. Numbers k with this property are called Riesel numbers, and analogous numbers with the minus sign replaced by a plus are called Sierpinski numbers of the second kind. The smallest known Riesel number is $k = 509,203$, but there remain 963 smaller candidates (the smallest of which is 659) which generate only composite numbers for all n which have been checked (Ribenboim 1996, p. 358).

Let $a(k)$ be smallest n for which $(2k-1) \cdot 2^n - 1$ is prime, then the first few values are 2, 0, 2, 1, 1, 2, 3, 1, 2, 1, 1, 4, 3, 1, 4, 1, 2, 2, 1, 3, 2, 7, ... (Sloane's A046069), and second smallest n are 3, 1, 4, 5, 3, 26, 7, 2, 4, 3, 2, 6, 9, 2, 16, 5, 3, 6, 2553, ... (Sloane's A046070).

Riesz Representation Theorem

There are a couple of versions of this theorem. Basically, it says that any bounded linear functional T on the space of compactly supported continuous functions on X is the same as integration against a measure μ,

$$Tf = \int f \, d\mu.$$

Here, the integral is the Lebesgue integral.

Because linear functionals form a vector space, and are not "positive," the measure μ may not be a positive measure. But if the functional T is positive, in the sense that $f \geq 0$ implies that $Tf \geq 0$, then the measure μ is also positive. In the generality of complex linear functionals, the measure μ is a complex measure. The measure μ is uniquely determined by T and has the properties of a regular Borel measure. It must be a finite measure, which corresponds to the boundedness condition on the functional. In fact, the norm of T, $\|T\|$, is the total variation measure of X, $|\mu|(X)$.

Naturally, there are some hypotheses necessary for this to make sense. The space X has to be locally compact and Hausdorff, which is not a strong restriction. In fact, for unbounded spaces X, the theorem also applies to functionals on continuous functions which vanish at infinity, in the sense that for any $\epsilon > 0$, there is a compact set K such that for any x not in K, $|f(x)| < \epsilon$ (which is the notion from calculus of $\lim_{x\to\infty} f(x) = 0$).

The Riesz representation theorem is useful in describing the DUAL SPACE to any space which contains the compactly supported continuous functions as a DENSE subspace. Roughly speaking, a linear functional is modified, usually by convolving with a bump function, to a bounded linear functional on the compactly supported continuous functions. Then it can be realized as integration against a measure. Often the measure must be ABSOLUTELY CONTINUOUS, and so the dual is integration against a function.

Riesz-Fischer Theorem

A function is L_2- (square-) integrable IFF its FOURIER SERIES is L_2-convergent. The application of this theorem requires use of the LEBESGUE INTEGRAL.

See also LEBESGUE INTEGRAL

Riesz's Theorem

Every continuous linear functional $U[f]$ for $f \in C[a, b]$ can be expressed as a STIELTJES INTEGRAL

$$U[f] = \int_a^b f(x)\,dw(x),$$

where $w(x)$ is determined by U and is of bounded variation on $[a, b]$.

See also STIELTJES INTEGRAL

Riffle Shuffle

A SHUFFLE, also called a FARO SHUFFLE, in which a deck of $2n$ cards is divided into two HALVES which are then alternatively interleaved from the left and right hands (an "in-shuffle") or from the right and left hands (an "out-shuffle"). Using an "in-shuffle," a deck originally arranged as 1 2 3 4 5 6 7 8 would become 5 1 6 2 7 3 8 4. Using an "out-shuffle," the deck order would become 1 5 2 6 3 7 4 8. Riffle shuffles are used in card tricks (Marlo 1958ab, Adler 1973), and also in the theory of parallel processing (Stone 1971, Chen *et al.* 1981).

In general, card k moves to the position originally occupied by the $2k$th card (mod $2n+1$). Therefore, in-shuffling $2n$ cards $2n$ times (where $2n+1$ is PRIME) results in the original card order. Similarly, out-shuffling $2n$ cards $2n-2$ times (where $2n-1$ is PRIME) results in the original order (Diaconis *et al.* 1983, Conway and Guy 1996). Amazingly, this means that an ordinary deck of 52 cards is returned to its original order after 8 out-shuffles.

Morris (1994) further discusses aspects of the perfect riffle shuffle (in which the deck is cut exactly in half and cards are perfectly interlaced). Ramnath and Scully (1996) give an algorithm for the shortest sequence of in- and out-shuffles to move a card from arbitrary position i to position j. This algorithm works for any deck with an EVEN number of cards and is $\mathcal{O}(\log n)$.

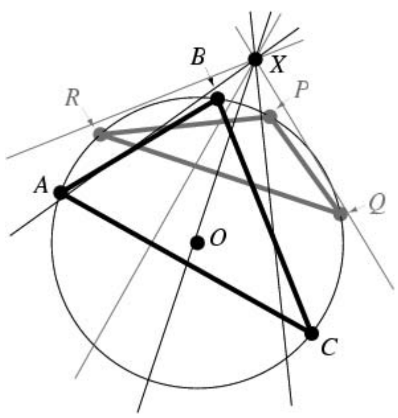
Rigby Points

The PERSPECTIVE CENTERS of the TANGENTIAL and CONTACT TRIANGLES of the inner and outer SODDY POINTS. The inner Ri and outer Ri' Rigby points are given by



$$Ri = I + \tfrac{4}{3}\,Ge$$

$$Ri' = I - \tfrac{4}{3}\, Ge,$$

where I is the INCENTER and Ge is the GERGONNE POINT.

Honsberger (1995) defines a different point which he calls the "Rigby point" X. Let QR be an arbitrary CHORD of the CIRCUMCIRCLE of a given TRIANGLE ΔABC, and let P be the POLE of the SIMSON LINE S_P with respect to ΔABC which is PERPENDICULAR to QR. Then it also turns out that $S_Q \perp PR$ and $S_R \perp PQ$. In addition, $S_A \perp BC$, $S_B \perp AC$, and $S_C \perp AB$ with respect to ΔPQR.

As a result of these remarkable facts, it can be shown that the SIMSON LINES S_P, S_Q, and S_R with respect to ΔABC meet in the Rigby point X. Moreover, the SIMSON LINES S_A, S_B, and S_C with respect to ΔPQR also meet in X, and X is the ORTHOPOLE of AB, BC, and AC with respect to ΔPQR, and of PQ, QR, and PR with respect to ΔABC. Finally, X is the MIDPOINT of the ORTHOCENTERS of ΔABC and ΔPQR (Honsberger 1996, p. 136).

Right Angle

An ANGLE equal to half the ANGLE from one end of a line segment to the other. A right angle is $\pi/2$ radians or $90°$. A TRIANGLE containing a right angle is called a RIGHT TRIANGLE. However, a TRIANGLE cannot contain more than one right angle, since the sum of the two right angles plus the third angle would exceed the $180°$ total possessed by a TRIANGLE.

The patterns of cracks observed in mud which has been dried by the sun form curves which intersect in right angles (Williams 1979, p. 45; Steinhaus 1983, p. 88; Pearce 1990, p. 12).

Right Cone

CONE

Right Conoid

A RULED SURFACE is called a right conoid if it can be generated by moving a straight LINE intersecting a fixed straight LINE such that the LINES are always PERPENDICULAR (Kreyszig 1991, p. 87). Taking the PERPENDICULAR plane as the xy-plane and the line to be the x-AXIS gives the PARAMETRIC EQUATIONS

$$x(u, v) = v \cos \vartheta(u)$$

$$y(u, v) = v \sin \vartheta(u)$$

$$z(u, v) = h(u)$$

(Gray 1997). Taking $h(u) = 2u$ and $\vartheta(u) = u$ gives the HELICOID.

Right Strophoid

The STROPHOID of a line L with pole O not on L and fixed point O' being the point where the PERPENDICULAR from O to L cuts L is called a right strophoid. It is therefore a general STROPHOID with $a = \pi/2$. The right strophoid is given by the Cartesian equation

$$y^2 = \frac{c - x}{c + x} x^2, \tag{1}$$

or the polar equation

$$r = c \cos(2\theta) \sec \theta. \tag{2}$$

The parametric form of the strophoid is

$$x(t) = \frac{1 - t^2}{t^2 + 1} \tag{3}$$

$$y(t)=\frac{t(t^2-1)}{t^2+1}. \tag{4}$$

The right strophoid has CURVATURE

$$\kappa(t)=-\frac{4(1+3t^2)}{(1+6t^2+t^4)^{3/2}} \tag{5}$$

and TANGENTIAL ANGLE

$$\phi(t)=-2\tan^{-1}t-\tan^{-1}\left(\frac{2t}{1+t^2}\right). \tag{6}$$

The right strophoid first appears in work by Isaac Barrow in 1670, although Torricelli describes the curve in his letters around 1645 and Roberval found it as the LOCUS of the focus of the conic obtained when the plane cutting the CONE rotates about the tangent at its vertex (MacTutor Archive). The AREA of the loop is

$$A_{\text{loop}}=\tfrac{1}{2}c^2(4-\pi) \tag{7}$$

(MacTutor Archive).

Let C be the CIRCLE with center at the point where the right strophoid crosses the X-AXIS and radius the distance of that point from the origin. Then the right strophoid is invariant under inversion in the CIRCLE C and is therefore an ANALLAGMATIC CURVE.

Right Strophoid Inverse Curve

The INVERSE CURVE of a right strophoid is the same strophoid.

Right Triangle

general right triangle *isosceles right triangle* *30–60–90° triangle*

A TRIANGLE with an ANGLE of 90° ($\pi/2$ radians). The sides a, b, and c of such a TRIANGLE satisfy the PYTHAGOREAN THEOREM. The largest side is conventionally denoted c and is called the HYPOTENUSE. A TRIANGLE that is not a right triangle is sometimes called an OBLIQUE TRIANGLE.

For any three similar shapes on the sides of a right triangle,

$$A_1+A_2=A_3, \tag{1}$$

which is equivalent to the PYTHAGOREAN THEOREM.

For a right triangle with sides a, b, and HYPOTENUSE c, let r be the INRADIUS. Then

$$\tfrac{1}{2}ab=\tfrac{1}{2}ra+\tfrac{1}{2}rb+\tfrac{1}{2}rc=\tfrac{1}{2}r(a+b+c). \tag{2}$$

Solving for r gives

$$r=\frac{ab}{a+b+c}. \tag{3}$$

This can also be written in the equivalent forms

$$r=\sqrt{\tfrac{1}{2}(c-a)(c-b)} \tag{4}$$

$$=\tfrac{1}{2}(a+b-c). \tag{5}$$

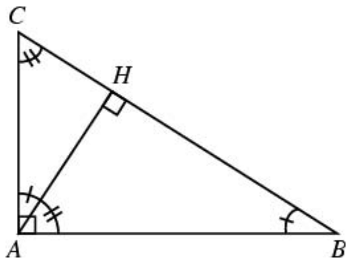
Now, since any PYTHAGOREAN TRIPLE can be written

$$a=m^2-n^2 \tag{6}$$

$$b=2mn \tag{7}$$

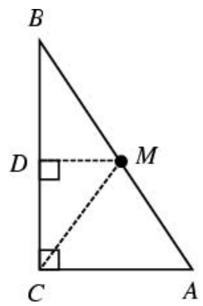
$$c=m^2+n^2, \tag{8}$$

(3) becomes



$$r=\frac{(m^2-n^2)2mn}{m^2-n^2+2mn+m^2+n^2}=n(m-n), \tag{9}$$

which is an INTEGER when m and n are integers (Ogilvy and Anderson 1988, p. 68).



The HYPOTENUSE of a right triangle is a DIAMETER of the triangle's CIRCUMCIRCLE, so the CIRCUMRADIUS is given by

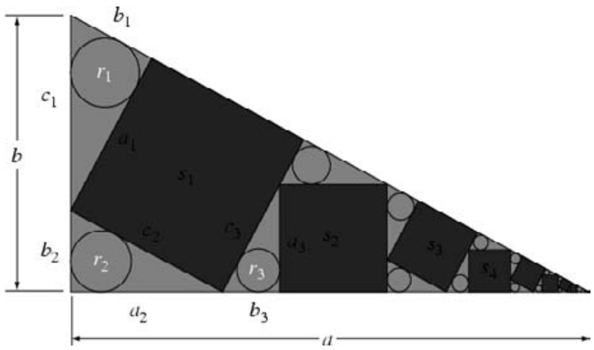
$$R=\tfrac{1}{2}c, \tag{10}$$

where c is the HYPOTENUSE.

Given a right triangle ΔABC, draw the ALTITUDE AH from the RIGHT ANGLE A. Then the triangles ΔAHC and ΔBHA are similar.

In a right triangle, the MIDPOINT of the HYPOTENUSE is equidistant from the three VERTICES (Dunham 1990). This can be proved as follows. Given ΔABC, let M be the MIDPOINT of AB (so that $AM = BM$). Draw $DM \| CA$, then since ΔBDM is similar to ΔBCA, it follows that $BD = DC$. Since both ΔBDM and ΔCDM are right triangles and the corresponding legs are equal, the HYPOTENUSES are also equal, so we have $AM = BM = CM$ and the theorem is proved.

Fermat showed how to construct an arbitrary number of equiareal nonprimitive right triangles. An analysis of PYTHAGOREAN TRIPLES demonstrates that the right triangle generated by a triple $(m_i^2 - n_i^2,\ 2m_i n_i,\ m_i^2 + n_i^2)$ has common AREA



$$A = rs(2r + s)(r + 2s)(r + s)(r - s)(r^2 + rs + s^2)$$

(Beiler 1966, pp. 126–127). The only EXTREMUM of this function occurs at $(r,\ s) = (0,\ 0)$. Since $A(r,\ s) = 0$ for $r = s$, the smallest AREA shared by three *nonprimitive* right triangles is given by $(r,\ s) = (1,\ 2)$, which results in an area of 840 and corresponds to the triplets (24, 70, 74), (40, 42, 58), and (15, 112, 113) (Beiler 1966, p. 126). One can also find quartets of right triangles with the same AREA. The QUARTET having smallest known area is (111, 6160, 6161), (231, 2960, 2969), (518, 1320, 1418), (280, 2442, 2458), with AREA 341,880 (Beiler 1966, p. 127). Guy (1994) gives additional information.

The smallest known AREA shared by three *primitive* right triangles is 13123110, corresponding to the triples (4485, 5852, 7373), (1380, 19019, 19069), and (3059, 8580, 9109) (Beiler 1966, p. 127; Gardner 1984, p. 160).

It is also possible to find sets of three and four Pythagorean triplets having the same PERIMETER (Beiler 1966, pp. 131–132). Lehmer (1900) showed that the number of primitive triples $N(p)$ with PERIMETER less than p is

$$\lim_{p\to\infty} N(p) = \frac{p \ln 2}{\pi^2} = 0.070230\ldots. \tag{11}$$

In a given right triangle, an infinite sequence of squares can be nested which alternately lie on the HYPOTENUSE and longest leg. These create a sequence of increasingly smaller similar right triangles. Let the original triangle have legs of lengths a and b and HYPOTENUSE of length $c = \sqrt{a^2 + b^2}$. Also define

$$x \equiv \frac{ac}{ab + c^2} \tag{12}$$

$$y \equiv \tfrac{1}{2}\sqrt{2[c^2 - (a + b)c + ab]}. \tag{13}$$

Then the sides of the n square are of length

$$s_n = bx^n. \tag{14}$$

Number the upper left triangle as 1, and then the remainder by following the "strip" of triangles at adjoining vertices. Then the side lengths of these triangles are

$$a_n = \begin{cases} s_{(n+1)/2} & \text{for } n \text{ odd} \\ \dfrac{ab}{c}\, x^{n/2} & \text{for } n \text{ even} \end{cases} \tag{15}$$

$$b_n = \begin{cases} \dfrac{b^2}{a}\, x^{(n+1)/2} & \text{for } n \text{ odd} \\ \dfrac{b^2}{c}\, x^{n/2} & \text{for } n \text{ even} \end{cases} \tag{16}$$

$$c_n = \begin{cases} \dfrac{bc}{a}\, x^{(n+1)/2} & \text{for } n \text{ odd} \\ s_{n/2} & \text{for } n \text{ even.} \end{cases} \tag{17}$$

The INRADII of the corresponding circles can be found from

$$r_n = \frac{1}{2}\sqrt{\frac{(b_n + c_n - a_n)(c_n + a_n - b_n)(a_n + b_n - c_n)}{a_n + b_n + c_n}}, \tag{18}$$

giving

$$r_n = \begin{cases} \frac{b}{a}\, yx^{(n+1)/2} & \text{for } n \text{ odd} \\ \frac{b}{c}\, yx^{n/2} & \text{for } n \text{ even.} \end{cases} \tag{19}$$

A SANGAKU PROBLEM from 1913 in the Miyagi Prefecture asks for the relationships between the first, third, and fifth inradii (Rothman 1998). This can be solved using elementary TRIGONOMETRY as well as the explicit equations given above, and has solution

$$r_3 = \sqrt{r_1 r_5}. \tag{20}$$

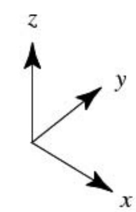
Right-Hand Rule



The rule which determines the orientation of the CROSS PRODUCT $\mathbf{u} \times \mathbf{v}$. The right-hand rule states that the orientation of the vectors' cross product is determined by placing $\mathbf{u}$ and $\mathbf{v}$ tail-to-tail, flattening the right hand, extending it in the direction of $\mathbf{u}$, and then curling the fingers in the direction that the angle $\mathbf{v}$ makes with $\mathbf{u}$. The thumb then points in the direction of $\mathbf{u} \times \mathbf{v}$.

A three-dimensional COORDINATE SYSTEM in which the axes satisfy the right-hand rule is called a RIGHT-HANDED COORDINATE SYSTEM, while one that does not is called a LEFT-HANDED COORDINATE SYSTEM.

Rigid Framework

FRAMEWORK, RIGID GRAPH

Rigid Graph

A FRAMEWORK (or GRAPH) is rigid IFF continuous motion of the points of the configuration maintaining the bar constraints comes from a family of motions of all EUCLIDEAN SPACE which are distance-preserving. A GRAPH that is not rigid is said to be FLEXIBLE (Maehara 1992).

For example, the CYCLE GRAPH C_3 is rigid, while C_4 is flexible. An embedding of the BIPARTITE GRAPH $K_{3,3}$ in the plane is rigid unless its six vertices lie on a CONIC (Bolker and Roth 1980, Maehara 1992).

A GRAPH G is (generically) d-rigid if, for almost all (i.e., an open dense set of) CONFIGURATIONS of p, the FRAMEWORK $G(p)$ is rigid in $\mathbb{R}^d$.

Cauchy (1813) proved the RIGIDITY THEOREM, one of the first results in rigidity theory. Although rigidity problems were of immense interest to engineers, intensive mathematical study of these types of problems has occurred only relatively recently (Connelly 1993, Graver *et al.* 1993).

Rigid Polyhedron

A POLYHEDRON is rigid if it cannot be continuously deformed into another configuration. A rigid polyhedron may have two or more stable forms which cannot be continuously deformed into each other without bending or tearing (Wells 1991).

A structure such as a polyhedron which can change form from one stable configuration to another with only a slight transient nondestructive elastic stretch is called MULTISTABLE (Goldberg 1978).

A non-rigid polyhedron may be "SHAKY" (infinitesimally movable) or FLEXIBLE. An example of a *concave* FLEXIBLE POLYHEDRON with 18 triangular faces was given by Connelly (1978), and a FLEXIBLE POLYHEDRON with only 14 triangular faces was subsequently found by Steffen (Mackenzie 1998).

JESSEN'S ORTHOGONAL ICOSAHEDRON is an example of a SHAKY POLYHEDRON.

Rigidity Theorem

If the faces of a *convex* POLYHEDRON were made of metal plates and the EDGES were replaced by hinges, the POLYHEDRON would be RIGID. The theorem was stated by Cauchy (1813), although a mistake in this paper went unnoticed for more than 50 years.

Rigorous

A proof or demonstration is said to be rigorous if the validity of each step and the connections between the steps is explicitly made clear is such a way that the result follows with certainty. "Rigorous" proofs often rely on the postulates and results of formal systems that are themselves considered rigorous under stated conditions.

Ring

A ring (in the mathematical sense) is a SET S together with two BINARY OPERATORS $+$ and $*$ (commonly interpreted as addition and multiplication, respectively) satisfying the following conditions:

1. Additive associativity: For all $a, b, c \in S$, $(a+b)+c = a+(b+c)$,
2. Additive commutativity: For all $a, b \in S$, $a+b = b+a$,
3. Additive identity: There exists an element $0 \in S$ such that for all $a \in S$, $0+a = a+0 = a$,
4. Additive inverse: For every $a \in S$ there exists $-a \in S$ such that $a+(-a) = (-a)+a = 0$,
5. Multiplicative associativity: For all $a, b, c \in S$, $a*(b*c) = a*(b*c)$,
6. Left and right distributivity: For all $a, b, c \in S$, $a*(b+c) = (a*b)+(a*c)$ and $(b+c)*a = (b*a)+(c*a)$.

A ring is therefore an ABELIAN GROUP under addition and a SEMIGROUP under multiplication.

The French word for a ring is *anneau*, and the German word is *Ring*, both meaning (not so surprisingly) "ring."

A ring must contain at least one element, but need not contain a multiplicative identity or be commutative. The number of finite rings of n elements for $n = 1, 2, ...$, are 1, 2, 2, 11, 2, 4, 2, 52, 11, 4, 2, 22, 2, 4, 4, ... (Sloane's A027623 and A037234; Fletcher 1980). In general, the number of rings of order p^3 for p an ODD PRIME is $3p+50$ and 52 for $p = 2$ (Ballieu 1947, Gilmer and Mott 1973).

A ring with a multiplicative identity is sometimes called a UNIT RING. Fraenkel (1914) gave the first abstract definition of the ring, although this work did not have much impact.

A ring that is COMMUTATIVE under multiplication, has a unit element, and has no divisors of zero is called an INTEGRAL DOMAIN. A ring which is also a COMMUTATIVE multiplication group is called a FIELD. The simplest rings are the INTEGERS $\mathbb{Z}$, POLYNOMIALS $\mathbb{R}[x]$ and $\mathbb{R}[x, y]$ in one and two variables, and SQUARE $n \times n$ REAL MATRICES.

Rings which have been investigated and found to be of interest are usually named after one or more of their investigators. This practice unfortunately leads to names which give very little insight into the relevant properties of the associated rings.

Ring Cyclide

The INVERSION of a RING TORUS. If the INVERSION CENTER lies on the torus, then the ring cyclide degenerates to a PARABOLIC RING CYCLIDE.

See also CYCLIDE, INVERSION, PARABOLIC CYCLIDE, RING CYCLIDE, RING TORUS, SPINDLE CYCLIDE, TORUS

Ring Direct Product

The direct product of the RINGS R_γ, for γ some INDEX SET I, is the set

$$\prod_{\gamma\in I} R_\gamma = \left\{ f : I \to \bigcup_{\gamma\in I} R_\gamma \,\middle|\, f(\gamma)\in R_\gamma \text{ all } \gamma\in I \right\}.$$

The ring direct product is confusingly also called the complete direct sum (Herstein 1968).

$$\begin{array}{ccc} X \to G & & X \to G\oplus H \to G \\ \downarrow & \Rightarrow & \downarrow \\ H & & H \end{array}$$

the universal property of a direct product; X factors through $G\oplus H$.

The ring direct product, like the GROUP DIRECT PRODUCT, has the UNIVERSAL PROPERTY that if any ring X has a HOMOMORPHISM to G and a homomorphism to H, then these homomorphisms factor through $G\times H$ in a unique way.

Ring Function

TOROIDAL FUNCTION

Ring Homomorphism

A ring homomorphism is a map $f: R\to S$ between two RINGS such that

1. Addition is preserved: $f(r_1+r_2)=f(r_1)+f(r_2)$,
2. The zero element is mapped to zero: $f(0_R)=0_S$, and
3. Multiplication is preserved: $f(r_1 r_2)=f(r_1)f(r_2)$,

where the operations on the left-hand side is in R and on the right-hand side in S. Note that a homomorphism must preserve the additive inverse map because $f(g)+f(-g)=f(g+-g)=f(0_R)=0_S$ so $-f(g)=f(-g)$.

See also GROUP HOMOMORPHISM, HOMOMORPHISM, ISOMORPHISM, RING

Ring of Polynomial

POLYNOMIAL RING

Ring Torus

One of the three STANDARD TORI given by the PARAMETRIC EQUATIONS

$$x=(c+a\cos v)\cos u$$

$$y=(c+a\cos v)\sin u$$

$$z=a\sin v$$

with $c>a$. This is the TORUS which is generally meant when the term "torus" is used without qualification. The inversion of a ring torus is a RING CYCLIDE if the INVERSION CENTER does not lie on the torus and a PARABOLIC RING CYCLIDE if it does. The above left figure shows a ring torus, the middle a cutaway, and the right figure shows a CROSS SECTION of the ring torus through the xz-plane.

Ringoid

A ringoid is a set R with two binary operators, conventionally denoted addition ($+$) and multiplication ($\times$), where $\times$ distributes over $+$ left and right:

$$a(b+c)=ab+ac$$

and

$$(b+c)a=ba+ca.$$

A ringoid can be empty.

Rising Factorial

There are two notations used for the falling and rising factorials, $(x)_n$ and $x^{(n)}$, which are unfortunately polar opposites of one another. The rising factorial $x^{(n)}$ (sometimes also denoted $\langle x \rangle_n$; Comtet 1974, p. 6), frequently called the POCHHAMMER SYMBOL in the theory of special functions, is defined by

$$x^{(n)} = x(x+1)\cdots(x+n-1). \quad (1)$$

It is related to the GAMMA FUNCTION $\Gamma(z)$ by

$$x^{(n)} = \frac{\Gamma(x+n)}{\Gamma(x)}, \quad (2)$$

where

$$x^{(0)} \equiv 1, \quad (3)$$

and is related to the FALLING FACTORIAL $(x)_n$ by

$$x^{(n)} = (-x)_n(-1)^n. \quad (4)$$

The rising factorial is implemented in *Mathematica* as `Pochhammer[x, n]`.

Note that in combinatorial usage, the FALLING FACTORIAL is denoted $(x)_n$ and the rising factorial is denoted $(x)^{(n)}$ (Comtet 1974, p. 6; Roman 1984, p. 5; Hardy 1999, p. 101), whereas in the calculus of FINITE DIFFERENCES and the theory of special functions, the FALLING FACTORIAL is denoted $x^{(n)}$ and the rising factorial is denoted $(x)_n$ (Roman 1984, p. 5; Abramowitz and Stegun 1972, p. 256; Spanier 1987). Extreme caution is therefore needed in interpreting the meanings of the notations $(x)_n$ and $x^{(n)}$. *In this work, the notation $x^{(n)}$ is used for the rising factorial*, despite the fact that POCHHAMMER SYMBOL, which is another name for the rising factorial, is universally denoted $(x)_n$.

The rising factorial arises in series expansions of HYPERGEOMETRIC FUNCTIONS and GENERALIZED HYPERGEOMETRIC FUNCTIONS. The first few rising factorials are

$$\begin{aligned}
x^{(0)} &= 1\\
x^{(1)} &= x\\
x^{(2)} &= x(x+1) = x^2+x\\
x^{(3)} &= x(x+1)(x+2) = x^3+3x^2+2x\\
x^{(4)} &= x(x+1)(x+2)(x+3) = x^4+6x^3+11x^2+6x.
\end{aligned}$$

Additional identities are

$$\frac{d}{dx}x^{(n)} = x^{(n)}[F(x+n-1)-F(x-1)] \quad (5)$$

$$x^{(n+k)} = (x+n)^k x^{(n)}, \quad (6)$$

where $F(z)$ is the DIGAMMA FUNCTION.

Robbins Algebra

Building on work of Huntington (1933), Robbins conjectured that the equations for a Robbins algebra, commutativity, associativity, and the ROBBINS AXIOM

$$!(!(x \vee y) \vee !(x \vee !y)) = x,$$

where $!x$ denotes NOT and $x \vee y$ denotes OR, imply those for a BOOLEAN ALGEBRA. The conjecture was finally proven using a computer (McCune 1997).

Robbins Axiom

The logical axiom

$$R(x, y) \equiv !(!(x \vee y) \vee !(x \vee !y)) = x,$$

where $!x$ denotes NOT and $x \vee y$ denotes OR, that, when taken together with associativity and commutativity, is equivalent to the axioms of BOOLEAN ALGEBRA.

The Robbins operator can be defined in *Mathematica* by

```
Robbins := Function[{x, y}, ! (! (! y \[Or] x)
\[Or] ! (x \[Or] y))]
```

That the Robbins axiom is a true statement in BOOLEAN ALGEBRA can be verified by examining its TRUTH TABLE.

ALTERNATING SIGN MATRIX

Robbins-Monro Stochastic Approximation

A STOCHASTIC APPROXIMATION method that functions by placing conditions on iterative step sizes and whose convergence is guaranteed under mild conditions. However, the method requires knowledge of the analytical gradient of the function under consideration.

Kiefer and Wolfowitz (1952) developed a finite difference version of the Robbins-Monro method which maintains the nice convergence properties, while obviating the need for knowledge of the analytic form of the gradient.

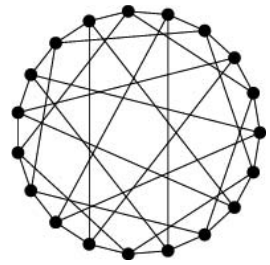
Robertson Conjecture



A conjecture due to M. S. Robertson (1936) which treats a UNIVALENT POWER SERIES containing only ODD powers within the UNIT DISK. This conjecture IMPLIES the BIEBERBACH CONJECTURE and follows in turn from the MILIN CONJECTURE. de Branges' proof of the BIEBERBACH CONJECTURE proceeded by proving the MILIN CONJECTURE, thus establishing the Robertson conjecture and hence implying the truth of the BIEBERBACH CONJECTURE.

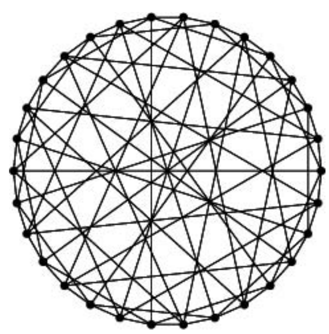
Robertson-Seymour Theorem



A generalization of the KURATOWSKI REDUCTION THEOREM by Robertson and Seymour, which states that the collection of finite GRAPHS is well-quasi-ordered by minor embeddability, from which it follows that Kuratowski's "forbidden minor" embedding obstruction generalizes to higher genus surfaces.

Formally, for a fixed INTEGER $g \geq 0$, there is a finite list of graphs $L(g)$ with the property that a GRAPH C embeds on a surface of genus g IFF it does not contain, as a minor, any of the GRAPHS on the list L.

Rodrigues' Curvature Formula

$$d\hat{\mathbf{N}} + \kappa_i \, d\mathbf{r} = \mathbf{0},$$

where $\hat{\mathbf{N}}$ is the unit NORMAL VECTOR and κ_i is one of the two PRINCIPAL CURVATURES.

See also NORMAL VECTOR, PRINCIPAL CURVATURES

Rodrigues Formula

An operator definition of a function. A Rodrigues formula may be converted into a SCHLÄFLI INTEGRAL.

See also RODRIGUES' CURVATURE FORMULA, RODRIGUES' ROTATION FORMULA, SCHLÄFLI INTEGRAL

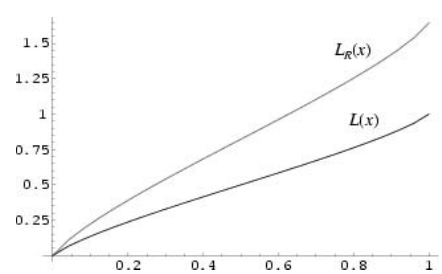
Rodrigues' Rotation Formula

This entry contributed by SERGE BELONGIE

Rodrigues' rotation formula gives an efficient method for computing the ROTATION MATRIX $\mathsf{R} \in SO(3)$ corresponding to a rotation by an angle $\theta \in \mathbb{R}$ about a fixed axis specified by the unit vector $\omega = (\omega_1, \omega_2, \omega_3) \in \mathbb{R}^3$. R is given by

$$e^{\hat{\omega}\theta} = 1 + \hat{\omega} \sin\theta + \hat{\omega}^2 (1 - \cos\theta),$$

where $\hat{\omega}$ denotes the SKEW SYMMETRIC MATRIX with entries



$$\hat{\omega} = \begin{bmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{bmatrix}.$$

Rogers L-Function

If $\mathrm{Li}_2(x)$ denotes the usual DILOGARITHM, then there are two variants that are normalized slightly differently, both called the Rogers L-function (Rogers 1907). Bytsko (1999) defines

$$L(x) = \frac{6}{\pi^2}\left[\mathrm{Li}_2(x) + \tfrac{1}{2}\ln x \ln(1-x)\right] \quad (1)$$

$$= \frac{6}{\pi^2}\left[\sum_{n=1}^{\infty} \frac{x^n}{n^2} + \tfrac{1}{2}\ln x \ln(1-x)\right], \quad (2)$$

(which he calls "the" dilogarithm), while Gordon and McIntosh (1997) and Loxton (1991, p. 287) define the

Rogers L-function as

$$L_R(x) = \mathrm{Li}_2(x) + \tfrac{1}{2}\ln x \ln(1-x) \tag{3}$$

$$= \frac{\pi^2}{6} L(x) \tag{4}$$

$$= \left[\sum_{n=1}^{\infty} \frac{x^n}{n^2} + \tfrac{1}{2}\ln x \ln(1-x)\right]. \tag{5}$$

The function $L(x)$ satisfies the concise identity

$$L(x) + L(1-x) = 1 \tag{6}$$

(Euler 1768), as well as ABEL'S FUNCTIONAL EQUATION

$$L(x) + L(y) = L(xy) + L\left(\frac{x(1-y)}{1-xy}\right) + L\left(\frac{y(1-x)}{1-xy}\right) \tag{7}$$

(Abel 1988, Bytsko 1999). The duplication formula for $L(x)$ follows from ABEL'S FUNCTIONAL EQUATION and is given by

$$\tfrac{1}{2} L(x^2) = L(x) - L\left(\frac{x}{1+x}\right). \tag{8}$$

The function has the nice INFINITE SERIES

$$\sum_{k=2}^{\infty} L\left(\frac{1}{k^2}\right) = \tfrac{1}{6}\pi^2 \tag{9}$$

(Lewin 1982; Loxton 1991, p. 298).
In terms of $L(x)$, the well-known dilogarithm identities become

$$L(0) = 0 \tag{10}$$

$$L(1-\rho) = \tfrac{2}{5} \tag{11}$$

$$L\left(\tfrac{1}{2}\right) = \tfrac{1}{2} \tag{12}$$

$$L(\rho) = \tfrac{3}{5} \tag{13}$$

$$L(1) = 1 \tag{14}$$

(Loxton 1991, pp. 287 and 289; Bytsko 1999), where $\rho = (\sqrt{5}-1)/2$.
Numbers $\theta \in (0, 1)$ which satisfy

$$\sum_{k=0}^{n} c_k L(\theta^k) = 0 \tag{15}$$

for some value of n are called L-ALGEBRAIC NUMBERS. Loxton (1991, p. 289) gives a slew of identities having rational coefficients

$$\sum_{k=0}^{n} \frac{e_k}{k} L(\theta^k) = c \tag{16}$$

instead of integers, where c is a RATIONAL NUMBER, a corrected and expanded version of which is summarized in the following table. In this table, polynomials $P(x)$ denote the real root of x. Many more similar identities can be found using INTEGER RELATION algorithms.

θ	e_k	c
1	1	1
$\frac{1}{2}$	1	$\frac{1}{2}$

x^3+x-1	$2, 6, 3, 0, 0, -3$	3
x^3-3x^2+4x-1	$5, -9, -6, 0, 0, 6$	1
x^3+x^2-1	$1, 6, 6, 0, 0, -6$	2
x^3+x^2+x-1	$1, 1, -3$	$\frac{1}{2}$
x^3+x^2+x-1	$2, 3, 0, -2$	$\frac{3}{2}$

Bytsko (1999) gives the additional identities

$$L(\lambda^{-2}) + L\left((\lambda^2-1)^{-2}\right) = \tfrac{4}{7} \quad (17)$$

$$L(\lambda^{-2}) + L\left((1+\lambda)^{-1}\right) = \tfrac{5}{7} \quad (18)$$

$$L\left(1-\frac{1}{\sqrt{2}}\right) + L\left(\sqrt{2}-1\right) = \tfrac{3}{4} \quad (19)$$

$$L(\sqrt{\rho}) + L\left(\frac{1}{1+\sqrt{\rho}}\right) = \tfrac{13}{11} \quad (20)$$

$$L\left(\tfrac{1}{2}-\tfrac{1}{2}\rho\right) + L(2\rho-1) = \tfrac{1}{2} \quad (21)$$

$$L\left(1-\tfrac{1}{2}\rho-\tfrac{1}{2}\sqrt{7\rho-3}\right) + L\left(\tfrac{1}{2}\sqrt{28\rho+45}-2\rho-\tfrac{2}{5}\right) = \tfrac{2}{5} \quad (22)$$

$$L(1-\delta^2) + L\left((1+\delta)^{-2}\right) = \tfrac{2}{5} \quad (23)$$

$$L\left(\tfrac{3}{2}-\tfrac{1}{2}\sqrt{2}-\tfrac{1}{2}\sqrt{2\sqrt{2}-1}\right) + L\left(\left(\tfrac{3}{2}+\sqrt{2}\right)\sqrt{2\sqrt{2}-1}-\tfrac{3}{2}-\tfrac{3}{2}\sqrt{2}\right) = \tfrac{1}{2} \quad (24)$$

$$L(\nu) - L(\mu^{-1}) = \tfrac{1}{7} \quad (25)$$

where

$$\lambda = 2\cos(\pi/7)$$

$$\rho = \left(\sqrt{5}-1\right)/2$$

$$\delta = \tfrac{1}{2}\left(\sqrt{3+2\sqrt{5}}-1\right),$$

with δ the positive root of

$$\delta^4+\delta^3-\delta-1=0 \quad (26)$$

and $0<\nu<1$ and $\mu>1$ the real roots of

$$t^6-7t^5+19t^4-28t^3+20t^2-7t+1=0. \quad (27)$$

Here, (17) and (18) are special cases of the WATSON IDENTITIES and (19) is a special case of ABEL'S DUPLICATION FORMULA with $x=1/\sqrt{2}$ (Gordon and McIntosh 1997, Bytsko 1999).

Rogers (1907) obtained a dilogarithm identity in m variables with m^2+1 terms which simplifies to Euler's identity for $m=1$ and ABEL'S FUNCTIONAL EQUATION for $m=2$ (Gordon and McIntosh 1997). For $m=3$, it is equivalent to

$$L(a)+L(b)+L(c)-L(u)-L(v) = L(abc)+L(ac/u)+L(bc/v)-L(av/u)-L(bu/v), \quad (28)$$

with

$$av(1-bc)+bu(1-ac)=uv(1-ab) \quad (29)$$

$$v(1-a)+u(1-b)=1-abc \quad (30)$$

(Gordon and McIntosh 1997).

Rogers-Ramanujan Continued Fraction

The Rogers-Ramanujan continued fraction is defined by

$$R(q) \equiv \cfrac{q^{1/5}}{1+\cfrac{q}{1+\cfrac{q^2}{1+\cfrac{q^3}{1+\cdots}}}} \quad (1)$$

(Rogers 1894, Ramanujan 1957, Berndt *et al.*). The coefficients of q^n in the MACLAURIN SERIES of $R(q)/q^{1/5}$ for $n=0, 1, 2, ...$ are 1, -1, 1, 0, -1, 1, -1, 1,

0, -1, 2, -3, ... (Sloane's A007325). The fraction can be given explicitly as

$$R(q) = q^{1/5} \frac{(q;\ q^5)_\infty (q^4;\ q^5)_\infty}{(q^2;\ q^5)_\infty (q^3;\ q^5)_\infty} \tag{2}$$

$$= q^{1/5} \prod_{k=1}^{\infty} \frac{(1 - x^{5k-1})(1 - x^{5k-4})}{(1 - x^{5k-2})(1 - x^{5k-3})} \tag{3}$$

$$= q^{1/5} \frac{f(-q,\ -q^4)}{f(-q^2,\ -q^3)}, \tag{4}$$

where $(a;q)_n$ is a Q-SERIES and $f(a,\ b)$ is a RAMANUJAN THETA FUNCTION.

$R(q)$ satisfies the amazing equalities

$$\frac{1}{R(q)} - 1 - R(q) = \frac{f(-q^{1/5})}{q^{1/5} f(-q^5)} \tag{5}$$

$$\frac{1}{[R(q)]^5} - 11 - [R(q)]^5 = \frac{[f(-q)]^6}{q[f(-q^5)]^6} \tag{6}$$

as well as

$$\sum_{n=-\infty}^{\infty} (-1)^n (10n+3) q^{(5n+3)n/2}$$

$$= \left[\frac{3}{[R(q)]^2} + [R(q)]^3\right] q^{2/5} \left[f(-q^5)\right]^3 \tag{7}$$

$$\sum_{n=-\infty}^{\infty} (-1)^n (10n+1) q^{(5n+1)n/2}$$

$$= \left[\frac{1}{[R(q)]^3} + 3[R(q)]^2\right] q^{3/5} \left[f(-q^5)\right]^3 \tag{8}$$

(Watson 1929ab; Berndt 1991, pp. 265–267; Berndt *et al.* , Son).

Defining

$$u = R(q) \tag{9}$$

$$u' = -R(-q) \tag{10}$$

$$v = R(q^2) \tag{11}$$

$$w = R(q^4), \tag{12}$$

these quantities satisfy the modular equations

$$uv^2 = \frac{v - u^2}{v + u^2} \tag{13}$$

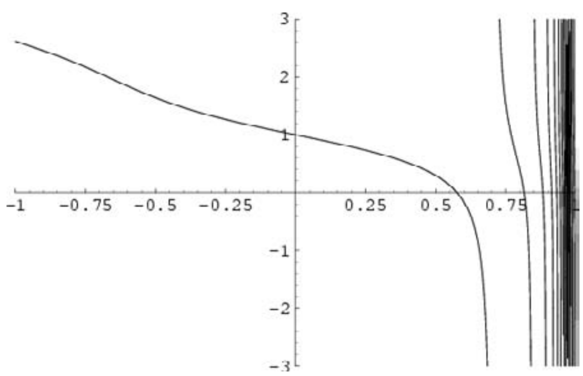
$$uw = \frac{w^2 - u^2 v}{w + u^2} \tag{14}$$

$$vw^2 = \frac{w - v^2}{w + v^2} \tag{15}$$

$$uu'v^2 = \frac{uu' - v}{u' - u} \tag{16}$$

$$u'w = \frac{u'^2 - w}{v^2 + w} \tag{17}$$

$$-vw = \frac{u'(v^2 - w)}{u'^2 v - w} \tag{18}$$



$$uu'v = \frac{u' - u}{v + uu'} \tag{19}$$

$$vw = \frac{u(v^2 - w)}{u^2 v - w} \tag{20}$$

(Berndt *et al.*).

As discussed by Hardy (1962, pp. xxvii and xxviii), Berndt and Rankin (1995), and Berndt *et al.*, Ramanujan also defined the generalized continued fraction

$$R(a,\ q) \equiv \cfrac{1}{1 + \cfrac{aq}{1 + \cfrac{aq^2}{1 + \cfrac{aq^3}{1 + \cdots}}}} \tag{21}$$

Ramanujan also considered

$$F(a,\ q) \equiv 1 - \cfrac{aq}{1 - \cfrac{aq^2}{1 - \cfrac{aq^3}{1 - \cdots}}}, \tag{22}$$

$$= \frac{\sum_{k=0}^{\infty} \frac{(-a)^k q^{k^2}}{(q)_k}}{\sum_{k=0}^{\infty} \frac{(-a)^k q^{k(k+1)}}{(q)_k}}. \tag{23}$$

(Berndt 1991, p. 30; Berndt *et al.*), of which the special case $F(q) = F(1,\ q)$ is plotted above. Terminating the terms in the continued fraction at a term aq^n gives

$$\frac{\sum_{k=0}^{\lfloor (n+1)/2\rfloor} \frac{(-a)^k q^{k^2}(q)_{n-k+1}}{(q)_k}}{\sum_{k=0}^{\lfloor n/2\rfloor} \frac{(-a)^k q^{(k+1)}(q)_{n-k}}{(q)_k (q)_{n-2k}}} = 1 - \cfrac{aq}{1 - \cfrac{aq^2}{1 - \cfrac{aq^3}{1 - \cdots - \cfrac{aq^n}{1}}}}, \tag{24}$$

(Berndt *et al.*). The real roots of $F(q)$ are 0.576149, 0.815600, 0.882493, 0.913806, 0.931949, 0.943785, 0.952125, ..., the smallest of which was found by Ramanujan (Berndt *et al.*). $F(q)$ and its smallest positive root are related to the enumeration of coins in a FOUNTAIN (Berndt 1991, Berndt *et al.*) and the study of birth and death processes (Berndt *et al.*, Parthasarathy *et al.* 1998). In general, the least positive root $q_0(a)$ of $F(a, q)$ is given as $a \to \infty$ by

$$q_0(a) \sim \frac{1}{a} - \frac{1}{a^2} + \frac{2}{a^3} - \frac{6}{a^4} + \frac{21}{a^5} - \frac{79}{a^6} + \frac{311}{a^7} - \frac{1266}{a^8} + \frac{5289}{a^9} - \frac{22553}{a^{10}} + \frac{97753}{a^{11}} - \ldots \tag{25}$$

(Berndt *et al.*). Ramanujan gave the amazing approximations

$$q_0(a) \sim \frac{2}{a - 1 + \sqrt{(a+1)(a+5)}} + \mathcal{O}(a^{-8}) \tag{26}$$

$$\sim \frac{1}{\frac{a - 1 + \sqrt{(a+1)(a+5)}}{2} + \left[\frac{a + 3 - \sqrt{(a+1)(a+5)}}{a - 1 + \sqrt{(a+1)(a+5)}}\right]^3} + \mathcal{O}(a^{-11}). \tag{27}$$

Rogers-Ramanujan Identities

For $|q| < 1$ and using the NOTATION of the RAMANUJAN THETA FUNCTION, the Rogers-Ramanujan identities are

$$\frac{f(-q^5)}{f(-q^2, -q^4)} = \sum_{k=0}^{\infty} \frac{q^{k^2}}{(q)_k} \tag{1}$$

$$\frac{f(-q^5)}{f(-q^2, -q^3)} = \sum_{k=0}^{\infty} \frac{q^{k(k+1)}}{(q)_k}, \tag{2}$$

where $(q)_k$ are q-SERIES. Written out explicitly (Hardy 1999, pp. 13 and 90),

$$1 + \frac{q}{1-q} + \frac{q^4}{(1-q)(1-q^2)} + \frac{q^9}{(1-q)(1-q^2)(1-q^3)} + \ldots$$

$$= \frac{1}{(1-q)(1-q^6)\ldots(1-q^4)(1-q^9)\ldots}$$

$$= 1 + x + x^2 + x^3 + 2x^4 + 2x^5 + 3x^6 + \ldots \tag{3}$$

(Sloane's A003114), and

$$1+\frac{q^2}{1-q}+\frac{q^6}{(1-q)(1-q^2)}+\frac{q^{12}}{(1-q)(1-q^2)(1-q^3)}+\ldots$$

$$=\frac{1}{(1-q^2)(1-q^7)\ldots(1-q^3)(1-q^8)\ldots}$$

$$=1+x^2+x^3+x^4+x^5+2x^6+\ldots \qquad (4)$$

(Sloane's A003106). These identities can also be written succinctly as

$$1+\sum_{k=1}^{\infty}\frac{q^{k^2+ak}}{(1-q)(1-q^2)\ldots(1-q^k)}$$

$$=\prod_{j=0}^{\infty}\frac{1}{(1-q^{5j+a+1})(1-q^{5j-a+4})} \qquad (5)$$

where $a = 0, 1$.

Other forms of the Rogers-Ramanujan identities include

$$\sum_k \frac{q^{k^2}}{(q;\, q)_k(q;\, q)_{n-k}}=\sum_k \frac{(-1)^k q^{(5k^2-k)/2}}{(q;\, q)_{n-k}(q;\, q)_{n+k}} \qquad (6)$$

and

$$\sum_k \frac{2q^{k^2}}{(q;\, q)_k(q;\, q)_{n-k}}=\sum_k \frac{(-1)^k(1+q^k)q^{(5k^2-k)/2}}{(q;\, q)_{n-k}(q;\, q)_{n+k}} \qquad (7)$$

(Petkovsek *et al.* 1996).

The formulas have a curious history, having been proved by Rogers (1894) in a paper that was completely ignored, then rediscovered (without proof) by Ramanujan sometime before 1913. The formulas were communicated to MacMahon, who published them in his famous text, still without proof. Then, in 1917, Ramanujan accidentally found Roger's 1894 paper while leafing through a journal. In the meantime, Schur (1917) independently rediscovered and published proofs for the identities (Hardy 1999, p. 91). Garsia and Milne (1981ab) gave the first proof of the Rogers-Ramanujan identities to construct a BIJECTION between the relevant classes of partitions (Andrews 1986, p. 59).

Schur showed that (3) has the combinatorial interpretation that the number of partitions of n with minimal difference $\geqslant 2$ is equal to the number of partitions into parts OF THE FORMS $5m+1$ or $5m+4$ (Hardy 1999, p. 92). The following table gives the first few values.

n	a_n	min. diff.	$\equiv 1, 4 \pmod 5$
1	1	1	1
2	1	2	1+1
3	1	3	1+1+1
4	2	4, 3+1	4, 1+1+1+1
5	2	5, 4+1	4+1, 1+1+1+1+1
6	3	6, 5+1, 4+2	5, 4+1+1, 1+1+1+1+1+1

There is a similar combinatorial interpretation for (4). A generalization of the Rogers-Ramanujan identities is given by

$$\sum_{n_1,\ldots,n_{k-1}\geqslant 0}\frac{x^{N_1^2+\cdots+N_{k-1}^2+N_i+\cdots+N_{k-1}}}{(x)_{n_1}\cdots(x)_{n_{k-1}}}$$

$$=\prod_{r\theta,\pm i \pmod{2k+1}}^{r=1}\frac{1}{1-x^r} \qquad (8)$$

where $1\leqslant i\leqslant k$, $k\geqslant 2$, x complex with $|x|<1$, and $N_j=n_j+\cdots n_{k-1}$ (Andrews 1984, p. 111; Fulman 1999). These identities have a number of important applications in mathematical physics (Fulman 1999).

Roller

CURVE OF CONSTANT WIDTH

Rolle's Theorem

Let f be differentiable on (a, b) and continuous on $[a, b]$. If $f(a)=f(b)=0$, then there is at least one point $c \in (a, b)$ where $f'(c)=0$.

See also FIXED POINT THEOREM, MEAN-VALUE THEOREM

Rolling Polygon

ROULETTE

Roman Coefficient

A generalization of the BINOMIAL COEFFICIENT whose NOTATION was suggested by Knuth,

$$\left\lfloor \begin{matrix} n \\ k \end{matrix} \right\rceil = \frac{\lfloor n \rceil !}{\lfloor k \rceil ! \lfloor n-k \rceil !}. \tag{1}$$

The above expression is read "Roman n choose k." Whenever the BINOMIAL COEFFICIENT is defined (i.e., $n \geq k \geq 0$ or $k \geq 0 > n$), the Roman coefficient agrees with it. However, the Roman coefficients are defined for values for which the BINOMIAL COEFFICIENTS are not, e.g.,

$$\left\lfloor \begin{matrix} n \\ -1 \end{matrix} \right\rceil = \frac{1}{\lfloor n+1 \rceil} \tag{2}$$

$$\left\lfloor \begin{matrix} 0 \\ k \end{matrix} \right\rceil = \frac{(-1)^{k+(k>0)}}{\lfloor k \rceil}, \tag{3}$$

where

$$n<0 \equiv \begin{cases} 1 & \text{for } n<0 \\ 0 & \text{for } n \geq 0. \end{cases} \tag{4}$$

The Roman coefficients also satisfy properties like those of the BINOMIAL COEFFICIENT,

$$\left\lfloor \begin{matrix} n \\ k \end{matrix} \right\rceil = \left\lfloor \begin{matrix} n \\ n-k \end{matrix} \right\rceil \tag{5}$$

$$\left\lfloor \begin{matrix} n \\ k \end{matrix} \right\rceil \left\lfloor \begin{matrix} k \\ r \end{matrix} \right\rceil = \left\lfloor \begin{matrix} n \\ r \end{matrix} \right\rceil \left\lfloor \begin{matrix} n-r \\ k-r \end{matrix} \right\rceil \tag{6}$$

an analog of PASCAL'S FORMULA

$$\left\lfloor \begin{matrix} n \\ k \end{matrix} \right\rceil = \left\lfloor \begin{matrix} n-1 \\ k \end{matrix} \right\rceil + \left\lfloor \begin{matrix} n-1 \\ k-1 \end{matrix} \right\rceil, \tag{7}$$

and a curious rotation/reflection law due to Knuth

$$(-1)^{k+(k>0)} \left\lfloor \begin{matrix} -n \\ k-1 \end{matrix} \right\rceil = (-1)^{n+(n>0)} \left\lfloor \begin{matrix} -k \\ n-1 \end{matrix} \right\rceil \tag{8}$$

(Roman 1992).

References

Roman, S. "The Logarithmic Binomial Formula." *Amer. Math. Monthly* **99**, 641–648, 1992.

Roman Factorial

$$\lfloor n \rceil ! \equiv \begin{cases} n! & \text{for } n \geq 0 \\ \dfrac{(-1)^{-n-1}}{(-n-1)!} & \text{for } n<0. \end{cases} \tag{1}$$

The Roman factorial arises in the definition of the HARMONIC LOGARITHM and ROMAN COEFFICIENT. It obeys the identities

$$\lfloor n \rceil ! = \lfloor n \rceil \lfloor n-1 \rceil ! \tag{2}$$

$$\frac{\lfloor n \rceil !}{\lfloor n-k \rceil !} = \lfloor n \rceil \lfloor n-1 \rceil \cdots \lfloor n-k+1 \rceil \tag{3}$$

$$\lfloor n \rceil ! \lfloor -n-1 \rceil ! = (-1)^{n+(n<0)}, \tag{4}$$

where

$$\lfloor n \rceil \equiv \begin{cases} n & \text{for } n \neq 0 \\ 1 & \text{for } n=0 \end{cases} \tag{5}$$

and

$$n < 0 \equiv \begin{cases} 1 & \text{for } n < 0 \\ 0 & \text{for } n \geq 0. \end{cases} \tag{6}$$

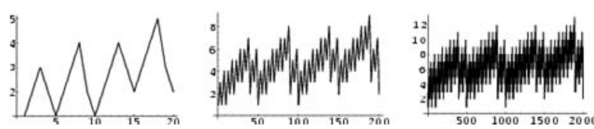
Roman Numeral

A system of numerical notations used by the Romans. It is an additive (and subtractive) system in which letters are used to denote certain "base" numbers, and arbitrary numbers are then denoted using combinations of symbols. Unfortunately, little is known about the origin of the Roman numeral system (Cajori 1993, p. 30).

Character	Numerical Value
I	1
V	5
X	10
L	50
C	100
D	500
M	1000



For example, the number 1732 would be denoted MDCCXXXII. One additional rule states that, instead of using four symbols to represent a 4, 40, 9, 90, etc., such numbers are instead denoted by preceding the symbol for 5, 50, 10, 100, etc., with a symbol indicating *subtraction.* For example, 4 is denoted IV, 9 as IX, 40 as XL, etc. However, this rule is generally *not* followed on the faces of clocks, where IIII is usually encountered instead of IV. Furthermore, the practice of placing smaller digits before large ones to indicate subtraction of value was hardly ever used by Romans and came into popularity in Europe after the invention of the printing press (Wells 1986, p. 60; Cajori 1993, p. 31).

For large numbers, the Romans placed a partial frame around numbers (open at the bottom), which indicated that the framed number was to be multiplied by 100,000, as illustrated above (Menninger 1992, p. 44; Cajori 1993, p. 32). In more recent practice, the strokes were sometimes written only on the sides, e.g., |X| (Cajori 19993, p. 32). It should also be noted that the Romans themselves never wrote M for 1000, but instead wrote (I) for 1,000, (I)(I) for 2,000, etc., and also occasionally wrote IM, IIM, etc. (Menninger 1992, p. 281; Cajori 1993, p. 32). However, in the Middle Ages, the use of M became quite common. The Romans sometimes used multiple parentheses to denote nested multiplications by 10, so (I) for 1,000, ((I)) for 10,000, (((I))) for 100,000, etc. (Cajori 1993, p. 33).

The Romans also occasionally used a vinculum (called a titulus in the Middle Ages) over a Roman numeral to indicate multiplication by 1000, so $\bar{\text{I}} = 1000$, $\overline{\text{II}} = 2000$, etc. (Menninger 1992, p. 281; Cajori 1993, p. 32).

Roman numerals are encountered in the release year for movies and occasionally on the numerals on the faces of watches and clocks, but in few other modern instances. They do have the advantage that addition can be done "symbolically" (and without worrying about the "place" of a given digit) by simply combining all the symbols together, grouping, writing groups of five Is as V, groups of two Vs as X, etc.

The number of characters in the Roman numerals for 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ... (i.e, I, II, III, IV, V, VI, VII, VIII, IX, X, ...) are 1, 2, 3, 2, 1, 2, 3, 4, 2, 1, 2, 3, 4, ... (Sloane's A006968). This leads to a scale-invariant fractal-like stairstep pattern which rises in steps then falls abruptly.

Roman Surface

A QUARTIC NONORIENTABLE SURFACE, also known as the STEINER SURFACE. The Roman surface is one of the three possible surfaces obtained by sewing a MÖBIUS STRIP to the edge of a DISK. The other two are the BOY SURFACE and CROSS-CAP, all of which are homeomorphic to the REAL PROJECTIVE PLANE (Pinkall 1986).

The center point of the Roman surface is an ordinary TRIPLE POINT with $(\pm 1,\ 0,\ 0)=(0,\ \pm 1,\ 0)=(0,\ 0,\ \pm 1)$, and the six endpoints of the three lines of self-intersection are singular PINCH POINTS, also known as WHITNEY SINGULARITIES. The Roman surface is essentially six CROSS-CAPS stuck together and contains a double INFINITY of CONICS.

The Roman surface can given by the equation

$$\left(x^2+y^2+z^2-k^2\right)^2=\left[(z-k)^2-2x^2\right]\left[(z+k)^2-2y^2\right]. \tag{1}$$

Solving for z gives the pair of equations

$$z=\frac{k(y^2-x^2)\pm(x^2-y^2)\sqrt{k^2-x^2-y^2}}{2(x^2+y^2)}. \tag{2}$$

If the surface is rotated by 45° about the z-AXIS via the ROTATION MATRIX

$$\mathsf{R}_z(45°)=\frac{1}{\sqrt{2}}\begin{bmatrix}1 & 1 & 0\\ -1 & 1 & 0\\ 0 & 0 & 1\end{bmatrix} \tag{3}$$

to give

$$\begin{bmatrix}x'\\ y'\\ z'\end{bmatrix}=\mathsf{R}_z(45°)\begin{bmatrix}x\\ y\\ z\end{bmatrix}, \tag{4}$$

then the simple equation

$$x^2y^2+x^2z^2+y^2z^2+2kxyz=0 \tag{5}$$

results. The Roman surface can also be generated using the general method for NONORIENTABLE SURFACES using the polynomial function

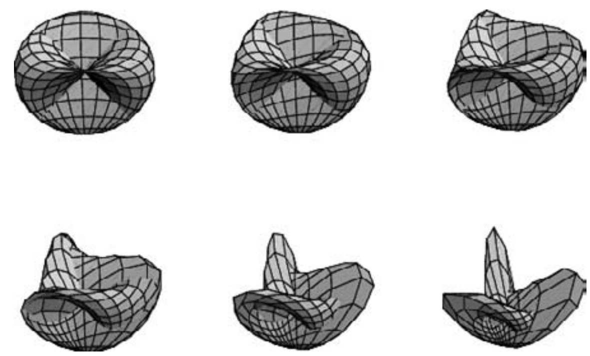
$$\mathbf{f}(x,\ y,\ z)=(xy,\ yz,\ zx) \tag{6}$$

(Pinkall 1986). Setting

$$x=\cos u\sin v \tag{7}$$

$$y=\sin u\sin v \tag{8}$$

$$z=\cos v \tag{9}$$



in the former gives

$$x(u,\ v)=\tfrac{1}{2}\sin(2u)\sin^2 v \tag{10}$$

$$y(u,\ v)=\tfrac{1}{2}\sin u\cos(2v) \tag{11}$$

$$z(u,\ v)=\tfrac{1}{2}\cos u\sin(2v) \tag{12}$$

for $u\in[0,\ 2\pi)$ and $v\in[-\pi/2,\ \pi/2]$. Flipping $\sin v$ and $\cos v$ and multiplying by 2 gives the form shown by Wang.

A HOMOTOPY (smooth deformation) between the Roman surface and BOY SURFACE is given by the equations

$$x(u,\ v)=\frac{\sqrt{2}\cos(2u)\cos^2 v+\cos u\sin(2v)}{2-\alpha\sqrt{2}\sin(3u)\sin(2v)} \tag{13}$$

$$y(u,\ v)=\frac{\sqrt{2}\sin(2u)\cos^2 v-\sin u\sin(2v)}{2-\alpha\sqrt{2}\sin(3u)\sin(2v)} \tag{14}$$

$$z(u,\ v)=\frac{3\cos^2 v}{2-\alpha\sqrt{2}\sin(3u)\sin(2v)} \tag{15}$$

for $u\in[-\pi/2,\ \pi/2]$ and $v\in[0,\ \pi]$ as α varies from 0 to 1. $\alpha=0$ corresponds to the Roman surface and $\alpha=1$ to the BOY SURFACE (Wang).

Rook Number

The rook numbers r_n^B of an $n \times n$ BOARD B are the number of subsets of size n such that no two elements have the same first or second coordinate. In other word, it is the number of ways of placing n rooks on B such that none attack each other. The rook numbers of a board determine the rook numbers of the complementary board $\bar{B}$, defined to be $\mathbf{d} \times \mathbf{d} \backslash B$. This is known as the ROOK RECIPROCITY THEOREM. The first few rook numbers are 1, 2, 7, 23, 115, 694, 5282, 46066, ... (Sloane's A000903). For an $n \times n$ board, each $n \times n$ PERMUTATION MATRIX corresponds to an allowed configuration of rooks.

Rooks Problem

The rook is a CHESS piece which may move any number of spaces either horizontally or vertically per move. The maximum number of nonattacking rooks which may be placed on an $n \times n$ CHESSBOARD is n. This arrangement is achieved by placing the rooks along the diagonal (Madachy 1979). The total number of ways of placing n nonattacking rooks on an $n \times n$ board is $n!$ (Madachy 1979, p. 47). The number of rotationally and reflectively inequivalent ways of placing n nonattacking rooks on an $n \times n$ board are 1, 2, 7, 23, 115, 694, ... (Sloane's A000903; Dudeney 1970, p. 96; Madachy 1979, pp. 46–54).

The minimum number of rooks needed to occupy or attack all spaces on an 8×8 CHESSBOARD is 8 (Madachy 1979), arranged in the same orientation as above.

Consider an $n \times n$ chessboard with the restriction that, for every subset of $\{1, \ldots, n\}$, a rook may not be put in column $s+j \pmod{n}$ when on row j, where the rows are numbered 0, 1, ..., $n-1$. Vardi (1991) denotes the number of rook solutions so restricted as rook(s, n). rook($\{1\}$, n) is simply the number of DERANGEMENTS on n symbols, known as a SUBFACTORIAL. The first few values are 1, 2, 9, 44, 265, 1854, ... (Sloane's A000166). rook($\{1, 2\}$, n) is a solution to the MARRIED COUPLES PROBLEM, sometimes known as MÉNAGE NUMBERS. The first few MÉNAGE NUMBERS are -1, 1, 0, 2, 13, 80, 579, ... (Sloane's A000179).

Although simple formulas are not known for general $\{1, \ldots, p\}$, RECURRENCE RELATIONS can be used to compute rook($\{1, \ldots, p\}$, n) in polynomial time for $p = 3, \ldots, 6$ (Metropolis *et al.* 1969, Minc 1978, Vardi 1991).

Room Square

A Room square (named after T. G. Room) of order n (for n EVEN) is an arrangement in an $(n-1)\times(n-1)$ SQUARE MATRIX of n objects such that each cell is either empty or holds exactly two different objects. Furthermore, each object appears once in each row and column and each unordered pair occupies exactly one cell. The Room square of order 2 is shown below.

1,2

The Room square of order 8 is

1,8			5,7		3,4	2,6
3,7	2,8			6,1		4,5
5,6	4,1	3,8			7,2	
	6,7	5,2	4,8			1,3
2,4		7,1	6,3	5,8		
	3,5		1,2	7,4	6,8	
		4,6		2,3	1,5	7,8

Root

The roots (sometimes also called "zeros") of an equation

$$f(x) = 0 \tag{1}$$

are the values of x for which the equation is satisfied.

The FUNDAMENTAL THEOREM OF ALGEBRA states that every POLYNOMIAL equation of degree n has exactly n roots, where some roots may have a multiplicity greater than 1 (in which case they are said to be degenerate). In *Mathematica*, the expression Root[f, k] represents the kth root of the POLYNOMIAL $f(x) = 0$.

To find the nth roots of a COMPLEX NUMBER, solve the equation $z^n = w$. Then

$$z^n = |z|^n[\cos(n\theta) + i\sin(n\theta)] = |w|(\cos\phi + i\sin\phi), \tag{2}$$

so

$$|z| = |w|^{1/n} \tag{3}$$

and

$$\arg(z) = \frac{\phi}{n}. \tag{4}$$

Rolle proved that any number has n nth roots (Boyer 1968, p. 476). Householder (1970) gives an algorithm for constructing root-finding algorithms with an arbitrary order of convergence. Special root-finding techniques can often be applied when the function in question is a POLYNOMIAL.

Root (Lie Algebra)

The roots of a SEMISIMPLE LIE ALGEBRA $\mathfrak{g}$ are the WEIGHTS occurring in its ADJOINT REPRESENTATION. The set of roots form the ROOT SYSTEM, and are completely determined by $\mathfrak{g}$. It is possible to choose a set of POSITIVE ROOTS, every root α is either positive or $-\alpha$ is positive. The SIMPLE ROOTS are the positive roots which cannot be written as a sum of positive roots.

The simple roots can be considered as a LINEARLY INDEPENDENT finite subset of EUCLIDEAN SPACE, and they generate the ROOT LATTICE. For example, in the SPECIAL LIE ALGEBRA $sl_2\mathbb{C}$ of two by two matrices with zero TRACE, has a basis given by the matrices

$$H=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix},\ X=\begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix},\ Y=\begin{bmatrix}0 & 0\\ 1 & 0\end{bmatrix}.$$

The ADJOINT REPRESENTATION is given by the BRACKETS

$$\mathrm{ad}(H(X))=[H,\ X]=2X$$

$$\mathrm{ad}(H(Y))=[H,\ Y]=-2Y,$$

so there are two roots of $\mathfrak{sl}_2$ given by $\alpha(H)=2$ and $-\alpha(H)=-2$. The RANK of $\mathfrak{sl}_2\mathbb{C}$ is one, and it has one positive root.

Root (Radical)

The nth root (or "nth RADICAL") of a quantity z is a value r such that $z=r^n$, and therefore is the INVERSE FUNCTION to the taking of a POWER. The nth root is denoted $r=\sqrt[n]{z}$ or, using POWER notation, $r=z^{1/n}$. The special case of the SQUARE ROOT is denoted $\sqrt{z}$.

The quantities for which a general FUNCTION equals 0 are also called ROOTS, or sometimes ZEROS.

See also CUBE ROOT, RADICAL, ROOT, SQUARE ROOT, VINCULUM

Root (Tree)

ROOT NODE

Root Dragging Theorem

If any of the ROOTS of a POLYNOMIAL are increased, then *all* of the critical points increase.

References

Anderson, B. "Polynomial Root Dragging." *Amer. Math. Monthly* **100**, 864–866, 1993.

Root Extraction

The operation of taking an nth ROOT of a number.

See also ADDITION, DIVISION, MULTIPLICATION, ROOT (RADICAL), SUBTRACTION

Root Lattice

The root lattice of a SEMISIMPLE LIE ALGEBRA is the DISCRETE LATTICE generated by the ROOTS in $\mathfrak{h}^*$, the DUAL SPACE to the CARTAN SUBALGEBRA.

Root Linear Coefficient Theorem

The sum of the reciprocals of ROOTS of an equation equals the NEGATIVE COEFFICIENT of the linear term in the MACLAURIN SERIES.

See also NEWTON'S RELATIONS

Root Node

A special node which is designated to turn a TREE into a ROOTED TREE. The root is sometimes also called "EVE" or an "ENDPOINT" (Saaty and Kainen 1986, p. 30) and each of the nodes which is one EDGE further away from a given EDGE is called a CHILD. Nodes connected to the same node are then called SIBLINGS.

See also CHILD, ROOTED TREE, SIBLING, TREE

Root of Unity

The nth ROOTS of UNITY are ROOTS $e^{2\pi ik/n}$ of the CYCLOTOMIC EQUATION

$$x^n = 1,$$

which are known as the DE MOIVRE NUMBERS. The notations ζ_k, ϵ_k, and ϵ_k are variously used to denote the kth nth root of unity.

+1 is always an nth root of unity, but -1 is such a root only if n is even.

See also CYCLOTOMIC EQUATION, CYCLOTOMIC POLYNOMIAL, DE MOIVRE'S IDENTITY, DE MOIVRE NUMBER, PRIMITIVE ROOT OF UNITY, PRINCIPAL ROOT OF UNITY, UNITY

Root System

Let E be a Euclidean space, $(\beta,\ \alpha)$ be the dot product, and denote the reflection in the hyperplane $P_\alpha = \{\beta \in E | (\beta,\ \alpha) = 0\}$ by

$$\sigma_\alpha(\beta) = \beta - 2(\beta,\ \alpha)/(\alpha,\ \alpha)\alpha = \beta - \langle\beta,\ \alpha\rangle\alpha,$$

where

$$\langle\beta,\ \alpha\rangle = \frac{2(\beta,\ \alpha)}{(\alpha,\ \alpha)}.$$

Then a subset R of the Euclidean space E is called a root system in E if:

1. R is finite, SPANS E, and does not contain 0,
2. If $\alpha \in R$, the reflection σ_α leaves R invariant, and
3. If $\alpha,\ \beta \in R$, then $\langle\beta,\ \alpha\rangle \in \mathbb{Z}$.

The ROOTS of a SEMISIMPLE LIE ALGEBRA are a root system, in a real subspace of the DUAL SPACE to the CARTAN SUBALGEBRA. In this case, the reflections W_α generate the WEYL GROUP, which is the symmetry group of the root system.

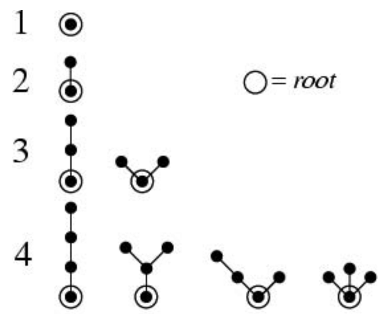
Root Test

Let u_k be a SERIES with POSITIVE terms, and let

$$\rho \equiv \lim_{k\to\infty} u_k^{1/k}.$$

1. If $\rho < 1$, the SERIES CONVERGES.
2. If $\rho > 1$ or $\rho = \infty$, the SERIES DIVERGES.
3. If $\rho = 1$, the SERIES may CONVERGE or DIVERGE.



This test is also called the Cauchy root test.

See also CONVERGENCE TESTS

Rooted Tree

rooted trees

A TREE with a single special ("labeled"rpar; node called the "ROOT" or "eve." A tree which is not rooted is sometimes called a FREE TREE. Denote the number of rooted trees with n nodes by T_n, then the GENERATING FUNCTION is

$$T(x) \equiv \sum_{n=0}^{\infty} T_n x^n = x + x^2 + 2x^3 + 4x^4 + 9x^5 + 20x^6$$

$$+48x^7 + 115x^8 + 286x^9 + 719x^{10} + \ldots \quad (1)$$

(Sloane's A000081). This POWER SERIES satisfies

$$T(x) = x \exp\left[\sum_{r=1}^{\infty} \frac{1}{r} T(x^r)\right] \quad (2)$$

$$t(x) = T(x) - \tfrac{1}{2}\left[T^2(x) - T(x^2)\right], \quad (3)$$

where $t(x)$ is the GENERATING FUNCTION for unrooted TREES. A GENERATING FUNCTION for T_n can be written using a product involving *the sequence itself* as

$$x \prod_{n=1}^{\infty} \frac{1}{(1-x^n)^{T_n}} = \sum_{n=1}^{\infty} T_n x^n. \quad (4)$$

The number of rooted trees can also be calculated from the RECURRENCE RELATION

$$T_{i+1} = \frac{1}{i} \sum_{j=1}^{i} \left(\sum_{d|j} d T_d \right) T_{i-j+1}, \quad (5)$$

with $T_0 = 0$ and $T_1 = 1$, where the second sum is over all d which DIVIDE j (Finch).

Root-Mean-Square

The root-mean-square (RMS) of a variate x, sometimes called the QUADRATIC MEAN, is the SQUARE ROOT of the mean squared value of x:

$$R(x) \equiv \sqrt{\langle x^2 \rangle} \quad (1)$$

$$= \begin{cases} \sqrt{\dfrac{\sum_{i=1}^{n} x_i^2}{n}} & \text{for a discrete distribution} \\ \sqrt{\dfrac{\int P(x) x^2\, dx}{\int P(x)\, dx}} & \text{for a continuous distribution.} \end{cases} \quad (2)$$

Hoehn and Niven (1985) show that

$$R(a_1 + c,\ a_2 + c,\ \ldots,\ a_n + c) < c + R(a_1,\ a_2, \ldots,\ a_n) \quad (3)$$

for any POSITIVE constant c.

Physical scientists often use the term root-mean-square as a synonym for STANDARD DEVIATION when they refer to the SQUARE ROOT of the mean squared deviation of a signal from a given baseline or fit.

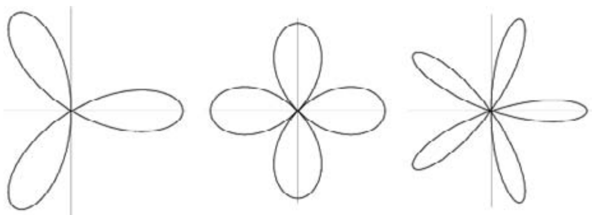
POLYNOMIAL ROOTS



Rosatti's Theorem

There is a one-to-one correspondence between the sets of equivalent correspondences (not of value 0) on an irreducible curve of GENUS (CURVE) p, and the rational COLLINEATIONS of a projective space of $2p-1$ dimensions which leave invariant a space of $p-1$ dimensions. The number of linearly independent correspondences will be that of linearly independent COLLINEATIONS.

Rose

A curve which has the shape of a petalled flower. This curve was named RHODONEA by the Italian mathematician Guido Grandi between 1723 and 1728 because it resembles a rose (MacTutor Archive). The polar equation of the rose is

$$r = a\ \sin(n\theta),$$

or

$$r = a\ \cos(n\theta).$$

If n is ODD, the rose is n-petalled. If n is EVEN, the rose is $2n$-petalled. If n is IRRATIONAL, then there are an infinite number of petals.
The QUADRIFOLIUM is the rose with $n = 2$. The rose is the RADIAL CURVE of the EPICYCLOID.

RotateLeft

CYCLIC PERMUTATION

RotateRight

CYCLIC PERMUTATION

Rotation

The turning of an object or coordinate system by an ANGLE about a fixed point. A rotation is an ORIENTATION-PRESERVING ORTHOGONAL TRANSFORMATION. EULER'S ROTATION THEOREM states that an arbitrary rotation can be parameterized using three parameters. These parameters are commonly taken as the EULER ANGLES. Rotations can be implemented using ROTATION MATRICES.

The rotation SYMMETRY OPERATION for rotation by $360°/n$ is denoted "n." For periodic arrangements of points (, the CRYSTALLOGRAPHY RESTRICTION gives the only allowable rotations as 1, 2, 3, 4, and 6.

Rotation Formula

A formula which transforms a given coordinate system by rotating it through a counterclockwise angle Φ about an axis $\hat{\mathbf{n}}$. This formula is used implicitly to transform objects in VRML (virtual reality markup language) using the command `Rotation` {*angle nx ny nz Phi*}. Referring to the above figure (Goldstein 1980), the equation for the "fixed" vector in the transformed coordinate system (i.e., the above figure corresponds to an ALIAS TRANSFORMATION), is

$$\mathbf{r}' = \overrightarrow{ON} + \overrightarrow{NV} + \overrightarrow{VQ} \tag{1}$$

$$= \hat{\mathbf{n}}(\hat{\mathbf{n}} \cdot \mathbf{r}) + [\mathbf{r} - \hat{\mathbf{n}}(\hat{\mathbf{n}} \cdot \mathbf{r})] \cos \Phi + (\mathbf{r} \times \hat{\mathbf{n}}) \sin \Phi \tag{2}$$

$$= \mathbf{r} \cos \Phi + \hat{\mathbf{n}}(\hat{\mathbf{n}} \cdot \mathbf{r})(1 - \cos \Phi) + (\mathbf{r} \times \hat{\mathbf{n}}) \sin \Phi \tag{3}$$

(Goldstein 1980; Varshalovich *et al.* 1988, p. 24). The ANGLE Φ and unit normal $\hat{\mathbf{n}}$ may also be expressed as EULER ANGLES. In terms of the EULER PARAMETERS,

$$\mathbf{r}' = \mathbf{r}(e_0^2 - e_1^2 - e_2^2 - e_3^2) + 2\mathbf{e}(\mathbf{e} \cdot \mathbf{r}) + 2(\mathbf{r} \times \mathbf{e})e_0. \tag{4}$$

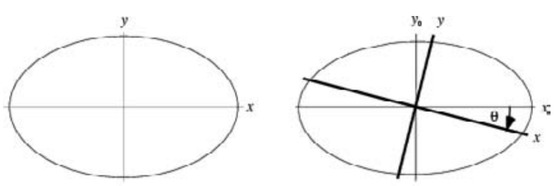
Rotation Group

There are three REPRESENTATIONS of the rotation groups, corresponding to EXPANSION/CONTRACTION, ROTATION, and SHEAR.

See also ROTATION MATRIX, SPECIAL ORTHOGONAL GROUP

Rotation Matrix

When discussing a ROTATION, there are two possible conventions: rotation of the *axes* and rotation of the *object* relative to fixed axes.



curve rotated by angle θ

In $\mathbb{R}^2$, let a curve be rotated by a clockwise ANGLE θ, so that the original axes of the curve are $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$, and the new axes of the curve are $\hat{\mathbf{x}}'$ and $\hat{\mathbf{y}}'$. The MATRIX transforming the original curve to the rotated curve, referred to the original $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$ axes, is

$$\mathsf{R}_\theta = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix}, \tag{1}$$

i.e.,

$$\mathbf{x} = \mathsf{R}_\theta \mathbf{x}'. \tag{2}$$

axes rotated by angle θ

On the other hand, let the *axes* with respect to which a curve is measured be rotated by a clockwise ANGLE θ, so that the original axes are $\hat{\mathbf{x}}_0$ and $\hat{\mathbf{y}}_0$, and the new axes are $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$. Then the MATRIX transforming the coordinates of the curve with respect to $\hat{\mathbf{x}}$ and $\hat{\mathbf{y}}$ is given by the MATRIX TRANSPOSE of the above matrix:

$$\mathsf{R}'_\theta = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}, \tag{3}$$

i.e.,

$$\mathbf{x} = \mathsf{R}'_\theta \mathbf{x}_0. \tag{4}$$

In $\mathbb{R}^3$, rotations of the x-, y-, and z-AXES give the matrices

$$\mathsf{R}_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{bmatrix} \tag{5}$$

$$\mathsf{R}_y(\beta) = \begin{bmatrix} \cos\beta & 0 & -\sin\beta \\ 0 & 1 & 0 \\ \sin\beta & 0 & \cos\beta \end{bmatrix} \tag{6}$$

$$\mathsf{R}_z(\gamma) = \begin{bmatrix} \cos\gamma & \sin\gamma & 0 \\ -\sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{7}$$

Any ROTATION can be given as a composition of rotations about three axes (EULER'S ROTATION THEOREM), and thus can be represented by a 3×3 MATRIX operating on a VECTOR,

$$\begin{bmatrix} x'_1 \\ x'_2 \\ x'_3 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}. \tag{8}$$

We wish to place conditions on this matrix so that it is consistent with an ORTHOGONAL TRANSFORMATION (basically, a ROTATION or ROTOINVERSION).

In a ROTATION, a VECTOR must keep its original length, so it must be true that

$$x'_i x'_i = x_i x_i \tag{9}$$

for $i = 1, 2, 3$, where EINSTEIN SUMMATION is being used. Therefore, from the transformation equation,

$$(a_{ij} x_j)(a_{ik} x_k) = x_i x_i. \tag{10}$$

This can be rearranged to

$$\begin{aligned} a_{ij}(x_j a_{ik}) x_k &= a_{ij}(a_{ik} x_j) x_k \\ &= a_{ij} a_{ik} x_j x_k = x_i x_i. \end{aligned} \tag{11}$$

In order for this to hold, it must be true that

$$a_{ij} a_{ik} = \delta_{jk} \tag{12}$$

for $j, k = 1, 2, 3$, where δ_{ij} is the KRONECKER DELTA. This is known as the ORTHOGONALITY CONDITION, and it guarantees that

$$\mathsf{A}^{-1} = \mathsf{A}^{\mathrm{T}}, \tag{13}$$

and

$$\mathsf{A}^{\mathrm{T}} \mathsf{A} = \mathsf{I}, \tag{14}$$

where A^{T} is the MATRIX TRANSPOSE and I is the IDENTITY MATRIX. Equation (14) is the identity which gives the orthogonal matrix its name. Orthogonal matrices have special properties which allow them to be manipulated and identified with particular ease.

Let A and B be two orthogonal matrices. By the ORTHOGONALITY CONDITION, they satisfy

$$a_{ij} a_{ik} = \delta_{jk}, \tag{15}$$

and

$$b_{ij} b_{ik} = \delta_{jk}, \tag{16}$$

where δ_{ij} is the KRONECKER DELTA. Now

$$c_{ij}c_{ik} = (ab)_{ij}(ab)_{jk} = a_{is}b_{sj}a_{it}b_{tk} = a_{is}a_{it}b_{sj}b_{tk}$$
$$= \delta_{st}b_{sj}b_{tk} = b_{tj}b_{tk} = \delta_{jk}, \quad (17)$$

so the product $C \equiv AB$ of two orthogonal matrices is also orthogonal.

The EIGENVALUES of an orthogonal matrix must satisfy one of the following:

1. All EIGENVALUES are 1.
2. One EIGENVALUE is 1 and the other two are -1.
3. One EIGENVALUE is 1 and the other two are COMPLEX CONJUGATES OF THE FORM $e^{i\theta}$ and $e^{-i\theta}$.

An orthogonal MATRIX A is classified as proper (corresponding to pure ROTATION) if

$$\det(A) = 1, \quad (18)$$

where det(A) is the DETERMINANT of A, or improper (corresponding to inversion with possible rotation; ROTOINVERSION) if

$$\det(A) = -1. \quad (19)$$

See also EULER ANGLES, EULER PARAMETERS, EULER'S ROTATION THEOREM, ROTATION, ROTATION FORMULA

Rotation Number

The period for a QUASIPERIODIC trajectory to pass through the same point in a SURFACE OF SECTION. If the rotation number is IRRATIONAL, the trajectory will densely fill out a curve in the SURFACE OF SECTION. If the rotation number is RATIONAL, it is called the WINDING NUMBER, and only a finite number of points in the SURFACE OF SECTION will be visited by the trajectory.

See also QUASIPERIODIC FUNCTION, SURFACE OF SECTION, WINDING NUMBER (MAP)

Rotation Operator

The rotation operator can be derived from examining an INFINITESIMAL ROTATION

$$\left(\frac{d}{dt}\right)_{\text{space}} = \left(\frac{d}{dt}\right)_{\text{body}} + \boldsymbol{\omega}\times,$$

where d/dt is the time derivative, $\boldsymbol{\omega}$ is the ANGULAR VELOCITY, and $\times$ is the CROSS PRODUCT operator.

See also ACCELERATION, ANGULAR ACCELERATION, INFINITESIMAL ROTATION

Roth's Removal Rule

If the matrices A, X, B, and C satisfy

$$AX - XB = C,$$

then

$$\begin{bmatrix} I & X \\ 0 & I \end{bmatrix}\begin{bmatrix} A & C \\ 0 & B \end{bmatrix}\begin{bmatrix} I & -X \\ 0 & I \end{bmatrix} = \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix},$$

where I is the IDENTITY MATRIX.

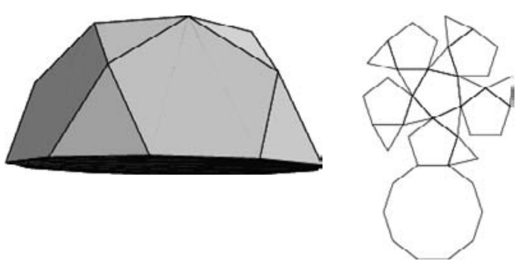
Rotoinversion

IMPROPER ROTATION

Rotor

A convex figure that can be rotated inside a POLYGON (or POLYHEDRON) while always touching every side (or face). The least AREA rotor in a SQUARE is the REULEAUX TRIANGLE. The least AREA rotor in an EQUILATERAL TRIANGLE is a LENS with two 60° ARCS of CIRCLES and RADIUS equal to the TRIANGLE ALTITUDE.



There exist nonspherical rotors for the TETRAHEDRON, OCTAHEDRON, and CUBE, but not for the DODECAHEDRON and ICOSAHEDRON.

Rotunda

A POLYHEDRON consisting of a n-gon, a parallel $2n$-gon rotated a half-edge turn, and a band of paired triangles separated by pentagons. The only true member giving a polyhedron consisting of all regular polygons with unit edge lengths is the PENTAGONAL ROTUNDA. It corresponds to half of an ICOSIDODECAHEDRON.

Rouché's Theorem

Given two functions f and g ANALYTIC in A with γ a simple loop HOMOTOPIC to a point in A, if $|g(z)| < |f(z)|$ for all z on γ, then f and $f+g$ have the same number of ROOTS inside γ.

A stronger version has been proved by Estermann (1962). The strong version also has a converse, as shown by Challener and Rubel (1982).

Roulette

The curve traced by a fixed point on a closed convex curve as that curve rolls without slipping along a second curve. The roulettes described by the FOCI of CONICS when rolled upon a line are sections of MINIMAL SURFACES (i.e., they yield MINIMAL SURFACES when revolved about the line) known as UNDULOIDS.

A particularly interesting case of a roulette is a regular n-gon rolling on a "road" composed of a sequence of truncated catenaries, as illustrated above. This motion is smooth in the sense that the CENTROID follows a straight line, although in the case of the rolling EQUILATERAL TRIANGLE, a physical model would be impossible to construct (Wagon 1991). For the rolling SQUARE, the shape of the road

is the CATENARY $y = -\cosh x$ truncated at $x = \pm\sinh^{-1} 1$ (Wagon 1991). For a regular n-gon, the Cartesian equation of the corresponding CATENARY is

$$y = -A \cosh\left(\frac{x}{A}\right), \tag{1}$$

where

$$A \equiv R \cos\left(\frac{\pi}{n}\right). \tag{2}$$

Round

NEAREST INTEGER FUNCTION, ROUND NUMBER, ROUNDNESS

Round Number

A number which is the product of a considerable number of comparatively small factors (Hardy 1999, p. 48). Round numbers are very rare. As Hardy (1999, p. 48) notes, "Half the numbers are divisible by 2, one-third by 3, one-sixth by both 2 and 3, and so on. Surely, then we may expect most numbers to have a *large* number of factors. But the facts seem to show the opposite."

See also HIGHLY COMPOSITE NUMBER, PRIME FACTORS, ROUNDNESS, SMOOTH NUMBER

References

Hardy, G. H. "Round Numbers." Ch. 3 in *Ramanujan: Twelve Lectures on Subjects Suggested by His Life and Work, 3rd ed.* New York: Chelsea, pp. 48–57, 1999.
Hoffman, P. *The Man Who Loved Only Numbers: The Story of Paul Erdos and the Search for Mathematical Truth.* New York: Hyperion, pp. 89–90, 1998.

Rounding

The process of approximating a quantity, be it for convenience or, as in the case of numerical computations, of necessity. If rounding is performed on each of a series of numbers in a long computation, ROUNDING ERROR can become important, especially if division by a small number ever occurs.

See also NEAREST INTEGER FUNCTION, ROUNDING ERROR, SHADOWING THEOREM

References

Mulliss, C. "Significant Figures and Rounding Rules." http://www.angelfire.com/oh/cmulliss/.
Wilkinson, J. H. *Rounding Errors in Algebraic Processes.* New York: Dover, 1994.

Rounding Error

The error produced in a computation by rounding results at one or more intermediate steps, resulting in a result different from that which would be obtained using exact numbers. The most common problems resulting from rounding error occur either when many steps are involved with rounding occurring at each step, when two quantities very close to each other are subtracted, or when a number is divided by a number which is close to zero.

An egregious example of rounding error is provided by a short-lived index devised at the Vancouver stock exchange. At its inception in 1982, the index was given a value of 1000.000. After 22 months of recomputing the index and truncating to three decimal places at each change in market value, the index stood at 524.881, despite the fact that its "true" value should have been 1009.811.

Other sorts of rounding error can also occur. A notorious example is the fate of the Ariane rocket launched on June 4, 1996. In the 37th second of flight, the inertial reference system attempted to convert a 64-bit floating point number to a 16-bit number, but instead triggered an overflow error which was interpreted by the guidance system as flight data, causing the rocket to veer off course and be destroyed. The Patriot missile defense system used during the Gulf War was also rendered ineffective due to roundoff error. The system used an integer timing register which was incremented at intervals of 0.1 s. However, the integers were converted to decimal numbers by multiplying by the BINARY approximation of 0.1,

$$0.00011001100110011001100_2 = \frac{209715}{2097152}.$$

As a result, after 100 hours $(3.6 \times 10^6$ ticks), an error of

$$\left(\frac{1}{10} - \frac{209715}{2097152}\right)(3600 \cdot 100 \cdot 10) = \frac{5625}{16384} \approx 0.3433 \text{ second}$$

had accumulated. This discrepancy caused the Patriot system to continuously recycle itself instead of targeting properly. As a result, an Iraqi Scud missile could not be targeted and was allowed to detonate on a barracks, killing 28 people.

See also ROUNDING

Roundness

Hoffman (1998, p. 90) calls the sum of the exponents in the PRIME FACTORIZATION of a number its roundness. The first few values for $n = 1, 2, \ldots$ are 0, 1, 1, 2, 1, 2, 1, 3, 2, 2, ... (Sloane's A001222).

See also HIGHLY COMPOSITE NUMBER, PRIME FACTORIZATION, ROUND NUMBER

Routh-Hurwitz Theorem

Consider the CHARACTERISTIC EQUATION

$$|\lambda \mathsf{I} - \mathsf{A}| = \lambda^n + b_1 \lambda^{n-1} + \ldots + b_{n-1}\lambda + b_n = 0$$

determining the n EIGENVALUES λ of a REAL $n \times n$ MATRIX A, where I is the IDENTITY MATRIX. Then the EIGENVALUES λ all have NEGATIVE REAL PARTS if

$$\Delta_1 > 0, \Delta_2 > 0, \ldots, \Delta_n > 0,$$

where

$$\Delta_k = \begin{vmatrix} b_1 & 1 & 0 & 0 & 0 & 0 & \cdots & 0 \\ b_3 & b_2 & b_1 & 1 & 0 & 0 & \cdots & 0 \\ b_5 & b_4 & b_3 & b_2 & b_1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{2k-1} & b_{2k-2} & b_{2k-3} & b_{2k-4} & b_{2k-5} & b_{k-6} & \cdots & b_k \end{vmatrix}.$$

Routh's Theorem

If the sides of a TRIANGLE are divided in the ratios $\lambda : 1$, $\mu : 1$, and $\nu : 1$, the CEVIANS form a central TRIANGLE whose AREA is

$$a = \frac{(\lambda\mu\nu - 1)^2}{(\lambda\mu + \lambda + 1)(\mu\nu + \mu + 1)(\nu\lambda + \nu + 1)}\delta, \qquad (1)$$

where δ is the AREA of the original TRIANGLE. for $\lambda =$

$\mu = \nu \equiv n$,

$$a = \frac{(n-1)^2}{n^2+n+1}\delta. \quad (2)$$

for $n = 1, 2, 3, \ldots$, the areas are 0, 1/7 (Steinhaus 1983, pp. 8–9), 4/13, 3/7, 16/31, 25/43, ... (Sloane's A046162 and A046163). The AREA of the TRIANGLE formed by connecting the division points on each side is

$$A' = \frac{\lambda\mu\nu + 1}{(\lambda+1)(\mu+1)(\nu+1)}\Delta. \quad (3)$$

Routh's theorem gives CEVA'S THEOREM and MENELAUS' THEOREM ($\lambda\mu\nu = -1$) as special cases.

Row-Convex Polyomino

row-convex   not row-convex

A row-convex polyomino is a self-avoiding CONVEX POLYOMINO such that the intersection of any horizontal line with the polyomino has at most two connected components. A row-convex polyomino is also called a horizontally convex polyomino. A COLUMN-CONVEX POLYOMINO is similarly defined.

See also COLUMN-CONVEX POLYOMINO, CONVEX POLYOMINO, POLYOMINO

RPN

REVERSE POLISH NOTATION

RSA Encryption

A PUBLIC-KEY CRYPTOGRAPHY ALGORITHM which uses PRIME FACTORIZATION as the TRAPDOOR ONE-WAY FUNCTION. Define

$$n \equiv pq \quad (1)$$

for p and q PRIMES. Also define a private key d and a public key e such that

$$de \equiv 1 \pmod{\phi(n)} \quad (2)$$

$$(e, \phi(n)) = 1, \quad (3)$$

where $\phi(n)$ is the TOTIENT FUNCTION, (a, b) denotes the GREATEST COMMON DIVISOR (so $(a, b) = 1$ means that a and b are RELATIVELY PRIME), and $a \equiv b \pmod{m}$ is a CONGRUENCE.

Let the message be converted to a number M. The sender then makes n and e public and sends

$$E = M^e \pmod{n}. \quad (4)$$

To decode, the receiver (who knows d) computes

$$E^d \equiv (M^e)^d \equiv M^{ed} \equiv M^{N\phi(n)+1} \equiv M \pmod{n}, \quad (5)$$

since N is an INTEGER. In order to crack the code, d must be found. But this requires factorization of n since

$$\phi(n) = (p-1)(q-1). \quad (6)$$

Both p and q should be picked so that $p \pm 1$ and $q \pm 1$ are divisible by large PRIMES, since otherwise the POLLARD P-1 FACTORIZATION METHOD or WILLIAMS $P+1$ FACTORIZATION METHOD potentially factor n easily. It is also desirable to have $\phi(\phi(pq))$ large and divisible by large PRIMES.

It is possible to break the cryptosystem by repeated encryption if a unit of $\mathbb{Z}/\phi(n)\mathbb{Z}$ has small ORDER (Simmons and Norris 1977, Meijer 1996), where $\mathbb{Z}/s\mathbb{Z}$ is the RING of INTEGERS between 0 and $s-1$ under addition and multiplication (mod s). Meijer (1996) shows that "almost" every encryption exponent e is safe from breaking using repeated encryption for factors OF THE FORM

$$p = 2p_1 + 1 \quad (7)$$

$$q = 2q_1 + 1, \quad (8)$$

where

$$p_1 = 2p_2 + 1 \quad (9)$$

$$q_1 = 2q_2 + 1, \tag{10}$$

and p, p_1, p_2, q, q_1, and q_2 are all PRIMES. In this case,

$$\phi(n) = 4p_1q_1 \tag{11}$$

$$\phi(\phi(n)) = 8p_2q_2. \tag{12}$$

Meijer (1996) also suggests that p_2 and q_2 should be of order 10^{75}.

Using the RSA system, the identity of the sender can be identified as genuine without revealing his private code.

RSA Number

Numbers contained in the "factoring challenge" of RSA Data Security, Inc. An additional number which is not part of the actual challenge is the RSA-129 number. The RSA numbers which have been factored are RSA-100 (Apr. 1991), RSA-110 (Apr. 1992), RSA-120 (Jun. 1993), RSA-129 (Apr. 1994), RSA-130 (Apr. 1996), RSA-140 (Feb. 1999), and RSA-155 (Aug. 1999; Peterson 1999). RSA-150 has not yet been factored.

RSA-129 is a 129-digit number used to encrypt one of the first public-key messages. This message was published by R. Rivest, A. Shamir, and L. Adleman (Gardner 1977), along with the number and a $100 reward for its decryption. Despite belief that the message encoded by RSA-129 "would take millions of years to break," RSA-129 was factored in 1994 using a distributed computation which harnessed networked computers spread around the globe performing a multiple polynomial QUADRATIC SIEVE factorization method. The effort was coordinated by P. Leylad, D. Atkins, and M. Graff. They received 112,011 full factorizations, 1,431,337 single partial factorizations, and 8,881,138 double partial factorizations out of a factor base of 524,339 PRIMES. The final MATRIX obtained was $188{,}346 \times 188{,}346$ square.

The text of the message was "The magic words are squeamish ossifrage" (an ossifrage is a rare, predatory vulture found in the mountains of Europe), and the FACTORIZATION (into a 64-DIGIT number and a 65-DIGIT number) is

$$\begin{aligned}&114381625757888867669235779976146612010218296\cdots\\&\cdots 721242362562561842935706935245733897830597 1\cdots\\&\cdots 2356395870505898907514759929002687954354 1\\=\,&3490529510847650949147849619903898133417764\cdots\\&\cdots 638493387843990820577\cdot 32769132993 26\cdots\\&\cdots 670954996198819083446141317764296799 2\cdots\\&\cdots 942539798288533\end{aligned}$$

(Leutwyler 1994, Cipra 1995).

On Feb. 2, 1999, a group led by H. te Riele completed factorization of RSA-140 into two 70-digits primes. Primality of the factors was proved using two different methods. The factorization was found using the NUMBER FIELD SIEVE factorization method, and beat the 130-digit record (for RSA-130) set on April 10, 1996. The amount of computer time spent on this factorization is estimated to be equivalent to 2000 MIPS years. (For the old 130-digit NFS-record, this effort is estimated to be 1000 MIPS years; te Riele 1999.) Sieving was done on about 125 SGI and Sun workstations running at 175 MHz on average, and on about 60 PCs running at 300 MHz on average. The total amount of CPU-time spent on sieving was 8.9 CPU years (te Riele 1999). Sieving started the day before Christmas 1998 and was completed one month later. The relations were collected and required 3.7 GB of memory (te Riele 1999) The filtering of the data and the building of the matrix took one calendar week. The resulting matrix had 4,671,181 rows and 4,704,451 columns, and weight 151,141,999 (32.36 nonzero entries per row). It took almost 100 CPU hours and 810 MB of central memory to find 64 dependencies among the rows of this matrix (te Riele 1999a).

On Aug. 22, 1999, a group led by H. te Riele completed factorization of RSA-155 into two 78-digit primes (te Riele 1999b, Peterson 1999). Primality of the factors was proved with the help of two different primality proving codes. This factorization was found using the NUMBER FIELD SIEVE factoring algorithm. The amount of computer time spent on this new factoring world record is estimated to be equivalent to 8000 MIPS years. Sieving was done on about 160 175–400 MHz SGI and Sun workstations, on 8 300 MHz SGI Origin 2000 processors, on about 120 300–450 MHz Pentium II PCs, and on 4 500 MHz Digital/Compaq boxes. The total amount of CPU-time spent

on sieving was 35.7 CPU years estimated to be equivalent to approximately 8000 MIPS years. Calendar time for sieving was 3 1/2 months. The filtering of the data and the building of the matrix were carried out at CWI and took one month. The resulting matrix had 6,699,191 rows, 6,711,336 columns, and weight 417,132,631 (62.27 nonzeros per row). It took 224 CPU hours and 2 GB of central memory on the Cray C916 at the SARA Amsterdam Academic Computer Center to find 64 dependencies among the rows of this matrix (te Riele 1999b).

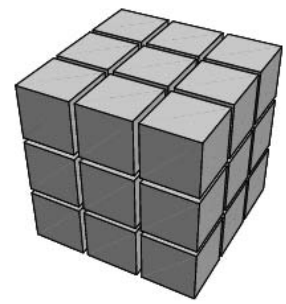
Rubber-Sheet Geometry

ALGEBRAIC TOPOLOGY

Rubik's Clock



A puzzle consisting of 18 small clocks. There are 12^{18} possible configurations, although not all are realizable.

See also RUBIK'S CUBE

References

Dénes, J. and Mullen, G. L. "Rubik's Clock and Its Solution." *Math. Mag.* **68**, 378–381, 1995.
Zeilberger, D. "Doron Zeilberger's Maple Packages and Programs: RubikClock." http://www.math.temple.edu/~zeilberg/programs.html.

Rubik's Cube

A $3 \times 3 \times 3$ CUBE in which the 26 subcubes on the outside are internally hinged in such a way that rotation (by a quarter turn in either direction or a half turn) is possible in any plane of cubes. Each of the six sides is painted a distinct color, and the goal of the puzzle is to return the cube to a state in which each side has a single color after it has been randomized by repeated rotations. The PUZZLE was invented in the 1970s by the Hungarian Erno Rubik and sold millions of copies worldwide over the next decade.

The number of possible positions of Rubik's cube is

$$\frac{8!12!3^8 2^{12}}{2 \cdot 3 \cdot 2} = 43{,}252{,}003{,}274{,}489{,}856{,}000$$

(Turner and Gold 1985, Schönert). Hoey showed using the PÓLYA-BURNSIDE LEMMA that there are 901,083,404,981,813,616 positions up to conjugacy by whole-cube symmetries.

Algorithms exist for solving a cube from an arbitrary initial position, but they are not necessarily optimal (i.e., requiring a minimum number of turns). The minimum number of turns required for an arbitrary starting position is still not known, although it is bounded from above. Michael Reid (1995) produced the best proven bound of 29 turns (or 42 "quarter-turns"). The proof involves large tables of "subroutines" generated by computer.

However, Dik Winter has produced a program based on work by Kociemba which has solved each of millions of cubes in at most 21 turns. Recently, Richard Korf (1997) has produced a different algorithm which is practical for cubes up to 18 moves away from solved. Out of 10 randomly generated cubes, one was solved in 16 moves, three required 17 moves, and six required 18 moves.

Rudin-Shapiro Sequence

Let a number n be written in BINARY as

$$n = (\epsilon_\kappa \epsilon_{k-1} \dots \epsilon_1 \epsilon_0)_2, \quad (1)$$

and define

$$b_n = \sum_{i=0}^{k-1} \epsilon_i \epsilon_{i+1} \quad (2)$$

as the number of DIGITS BLOCKS of 11s in the BINARY expansion of n. For $n = 0, 1, \dots, b_n$ is given by 0, 0, 1, 0, 0, 1, 2, 0, 0, 0, 1, 1, 1, 2, 3, ... (Sloane's A014081).

Now define

$$a_n = (-1)^{b_n} \quad (3)$$

as the parity of the number of pairs of consecutive 1s in the BINARY expansion of n. For $n = 0, 1, \dots$, the first few values are 1, 1, -1, 1, 1, -1, 1, 1, 1, 1, -1, -1, -1, ... (Sloane's A020985).

The SUMMATORY sequence of a_n is the defined by

$$s_n \equiv \sum_{i=0}^{n} a_i, \quad (4)$$

giving the first few terms 2, 3, 2, 3, 4, 3, 4, 5, 6, 7, 6, 5, 4, ... (Sloane's A020986). For the special case $n = 2^{k-1}$, s_n can be computed using the formula

$$s_n = \begin{cases} 2^{k/2} + 1 & \text{if } k \text{ is even} \\ 2^{(k-1)/2} + 1 & \text{if } k \text{ is odd} \end{cases} \quad (5)$$

(Blecksmith and Laud 1995), giving 2, 3, 3, 5, 5, 9, 9, 17, 17, 33, 33, 65, ... (Sloane's A051032).

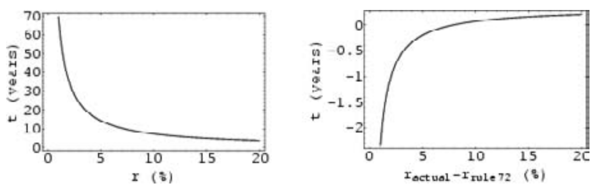
Ruffini-Horner Method



HORNER'S METHOD

Rule

A usually simple ALGORITHM or IDENTITY. The term is frequently applied to specific orders of NEWTON-COTES FORMULAS.

See also ALGORITHM, BAC-CAB RULE, BODE'S RULE, CHAIN RULE, CRAMER'S RULE, DESCARTES' SIGN RULE, DURAND'S RULE, ESTIMATOR, EULER'S RULE, EULER'S TOTIENT RULE, GOLDEN RULE, HARDY'S RULE, HORNER'S RULE, IDENTITY, L'HOSPITAL'S RULE, LEIBNIZ INTEGRAL RULE, METHOD, OSBORNE'S RULE, PASCAL'S RULE, POWER RULE, PRODUCT RULE, QUARTER SQUARES RULE, QUOTA RULE, QUOTIENT RULE, ROTH'S REMOVAL RULE, RULE OF 72, SIMPSON'S RULE, SLIDE RULE, SUM RULE, TRAPEZOIDAL RULE, WEDDLE'S RULE, ZEUTHEN'S RULE

Rule of 72

The time required for a given PRINCIPAL to double (assuming $n = 1$ CONVERSION PERIOD) for COMPOUND

INTEREST is given by solving

$$2P = P(1+r)^t, \quad (1)$$

or

$$t = \frac{\ln 2}{\ln(n+r)}, \quad (2)$$

where LN is the NATURAL LOGARITHM. This function can be approximated by the so-called "rule of 72":

$$t \approx \frac{0.72}{r}. \quad (3)$$

The above plots show the actual doubling time t (left plot) and the difference between the actual doubling time and the doubling time calculated using the rule of 72 (right plot) as a function of the interest rate r.

Ruled Surface

A SURFACE which can be swept out by a moving a LINE in space and therefore has a parameterization OF THE FORM

$$\mathbf{x}(v, v) = \mathbf{b}(u) + v\boldsymbol{\delta}(u), \quad (1)$$

where $\mathbf{b}$ is called the DIRECTRIX (also called the BASE CURVE) and $\boldsymbol{\delta}$ is the DIRECTOR CURVE. The straight lines themselves are called RULINGS. The rulings of a ruled surface are ASYMPTOTIC CURVES. Furthermore, the GAUSSIAN CURVATURE on a ruled REGULAR SURFACE is everywhere NONPOSITIVE.

Examples of ruled surfaces include the elliptic HYPERBOLOID of one sheet (a DOUBLY RULED SURFACE)

$$\begin{bmatrix} a(\cos u \mp v \sin u) \\ b(\sin u \pm v \cos u) \\ \pm cv \end{bmatrix} = \begin{bmatrix} a \cos u \\ b \sin u \\ 0 \end{bmatrix} \pm v \begin{bmatrix} -a \sin u \\ b \cos u \\ c \end{bmatrix}, \quad (2)$$

the HYPERBOLIC PARABOLOID (a DOUBLY RULED SURFACE)

$$\begin{bmatrix} a(u+v) \\ \pm bv \\ u^2 + 2uv \end{bmatrix} = \begin{bmatrix} au \\ 0 \\ u^2 \end{bmatrix} + v \begin{bmatrix} a \\ \pm b \\ 2u \end{bmatrix}, \quad (3)$$

PLÜCKER'S CONOID

$$\begin{bmatrix} r \cos\theta \\ r \sin\theta \\ 2\cos\theta \sin\theta \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 2\cos\theta \sin\theta \end{bmatrix} + r \begin{bmatrix} \cos\theta \\ \sin\theta \\ 0 \end{bmatrix}, \quad (4)$$

and the MÖBIUS STRIP

$$a \begin{bmatrix} \cos u + v \cos\left(\frac{1}{2} u\right) \cos u \\ \sin u + v \cos\left(\frac{1}{2} u\right) \sin u \\ v \sin\left(\frac{1}{2} u\right) \end{bmatrix} = a \begin{bmatrix} \cos u \\ \sin u \\ 0 \end{bmatrix} + au \begin{bmatrix} \cos u \left(\frac{1}{2} u\right) \cos u \\ \cos\left(\frac{1}{2} u\right) \sin u \\ \sin\left(\frac{1}{2} u\right) \end{bmatrix} \quad (5)$$

(Gray 1997).

The only ruled MINIMAL SURFACES are the PLANE and HELICOID (Catalan 1842, do Carmo 1986).

Ruler

A STRAIGHTEDGE with markings to indicate distances. Although GEOMETRIC CONSTRUCTIONS are sometimes said to be performed with a ruler and COMPASS, the term STRAIGHTEDGE is preferable to ruler since markings are not allowed by the classical Greek rules.

Rumors

GOSSIPING

Rumor Spreading

GOSSIPING

Run

A run is a sequence of more than one consecutive identical outcomes, also known as a CLUMP. Given n BERNOULLI TRIALS (say, in the form of COIN TOSSINGS), the probability $P_t(n)$ of a run of t consecutive heads or tails is given by the RECURRENCE RELATION

$$P_t(n) = P_t(n-1) + 2^{-t}[1 - P_t(n-t)], \qquad (1)$$

where $P_t(n) = 0$ for $n < t$ and $P_t(t) = 2^{1-t}$ (Bloom 1996).

Let $R(r, n)$ be the probability that a run of r consecutive heads appears in n independent tosses of a COIN. There is a beautiful formula for $R(r, n)$ given in terms of the coefficients of the GENERATING FUNCTION

$$F_p(r, s) = \frac{p^r s^r (1 - ps)}{1 - s + (1 - p)p^r s^{r+1}} \equiv \sum_{i=r}^{\infty} c_i^p s^i \qquad (2)$$

(Feller 1968, 2nd ed. p. 300), where $0 < p < 1$ is the probability of obtaining a head in a single toss. Then

$$R_p(r, n) = \sum_{i=r}^{n} c_i^p \qquad (3)$$

The following table gives the triangle of numbers $2^n R_{1/2}(r, n)$ for $r = 1, 2, \ldots$ and $n = r, r+1, \ldots, \ldots$ (Sloane's A050227).

$r\backslash n$	1	2	3	4	5	6	7	8
1	1	3	7	15	31	63	127	255
2	0	1	3	8	19	43	94	201
3	0	0	1	3	8	20	47	107
4	0	0	0	1	3	8	20	48
5	0	0	0	0	1	3	8	20
6	0	0	0	0	0	1	3	8
7	0	0	0	0	0	0	1	3
8	0	0	0	0	0	0	0	1

The special case $r = 2$ gives the sequence

$$R_2(n) = 2^{n+1} - F_{n+3}, \qquad (4)$$

where F_n is a FIBONACCI NUMBER, the first few terms of which for $n = 1, 2, \ldots$ are 0, 1, 3, 8, 19, 43, 94, 201, ... (Sloane's A008466). The first few $R_3(n)$ are given by 0, 0, 1, 3, 8, 20, 47, 107, 238, ... Sloane's A050231; the first few $R_4(n)$ are 0, 0, 0, 1, 3, 8, 20, 48, 111, 251, 558, ... (Sloane's A050232); and the first few $R_5(n)$ 0, 0, 0, 0, 1, 3, 8, 20, 48, 112, 255, 571, 1262, ... (Sloane's A050233).

Given n BERNOULLI TRIALS with a probability of success (heads) p, the expected number of tails is $n(1-p)$, so the expected number of tail runs ≥ 1 is $\approx n(1-p)p$. Continuing,

$$N_R = n(1-p)p^R \qquad (5)$$

is the expected number of runs $\geq R$. The longest expected run is therefore given by

$$R = \log_{1/p}[n(1-p)] \qquad (6)$$

(Gordon *et al.* 1986, Schilling 1990). Given m 0s and n 1s, the number of possible arrangements with u runs is

$$f_u = \begin{cases} 2\binom{m-1}{k-1}\binom{n-1}{k-1} & u \equiv 2k \\ \binom{m-1}{k-1}\binom{n-1}{k-2} + \binom{m-1}{k-2}\binom{n-1}{k-1} & u \equiv 2k+1 \end{cases} \qquad (7)$$

for k an INTEGER, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. Then

$$P(u \leq u') = \sum_{u=2}^{u'} \frac{f_u}{\binom{m+n}{m}}. \qquad (8)$$

Feller (1968, pp. 278–279) proved that for $w(n) \equiv 1 - R_{1/2}(3, n)$,

$$\lim_{n\to\infty} w(n)\alpha^{n+1} = \beta, \qquad (9)$$

where

$$\alpha = \tfrac{1}{3}\left[\left(136+24\sqrt{33}\right)^{1/3} - 8\left(136+24\sqrt{33}\right)^{-1/3} - 2\right]$$

$$= 1.087378025\ldots \quad (10)$$

and

$$\beta = \frac{2-\alpha}{4-3\alpha} = 1.236839845\ldots. \quad (11)$$

The corresponding constants for a RUN of $k > 1$ heads are α_k, the smallest POSITIVE ROOT of

$$1 - x + \left(\tfrac{1}{2}x\right)^{k+1} = 0, \quad (12)$$

and

$$\beta_k = \frac{2-\alpha}{k+1-k\alpha_k}. \quad (13)$$

These are modified for unfair coins with $P(H) = p$ and $P(T) = q = 1-p$ to α'_k, the smallest POSITIVE ROOT of

$$1 - x + qp^k x^{k+1} = 0, \quad (14)$$

and

$$\beta'_k = \frac{1 - p\alpha'_k}{(k+1-k\alpha'_k)p} \quad (15)$$

(Feller 1968, pp. 322–325).

Let $C_t(m, k)$ denote the number of sequences of m indistinguishable objects of type A and k indistinguishable objects of type B in which *no* t-run occurs. The probability that a t-run *does* occur is then given by

$$P_t(m, k) = 1 - \frac{C_t(m, k)}{\binom{m+k}{k}}, \quad (16)$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT. Bloom (1996) gives the following recurrence sequence for $C_t(m, k)$,

$$C_t(m, k) = \sum_{i=0}^{t-1} C_t(m-1, k-i) - \sum_{i=1}^{t-1} C_t(m-t, k-i) + e_t(m, k), \quad (17)$$

where

$$e_t(m, k) \equiv \begin{cases} 1 & \text{if } m = 0 \text{ and } 0 \le k < t \\ -1 & \text{if } m = t \text{ and } 0 \le k < t \\ 0 & \text{otherwise.} \end{cases} \quad (18)$$

Another recurrence which has only a fixed number of terms is given by

$$C_t(m, k) = C_t(m-1, k) + C_t(m, k-1) - C_t(m-t, k-1) - C_t(m-1, k-t) + C_t(m-t, k-t) + e_t^*(m, k), \quad (19)$$

where

$$e_t^*(m, k) \equiv \begin{cases} 1 & \text{if } (m, k) = (0, 0) \text{ or } (t, t) \\ -1 & \text{if } (m, k) = (0, t) \text{ or } (t, 0) \\ 0 & \text{otherwise} \end{cases} \quad (20)$$

(Goulden and Jackson 1983, Bloom 1996). These formulas disprove the assertion of Gardner (1982) that "there will almost always be a clump of six or seven CARDS of the same color" in a normal deck of cards by giving $P_6(26, 26) = 0.46424$.

Bloom (1996) gives the expected number of noncontiguous t-runs in a sequence of m 0s and n 1s as

$$E(n, m, t) = \frac{(m+1)(n)_t + (n+1)(m)_t}{(m+n)_t}, \quad (21)$$

where $(a)_n$ is the POCHHAMMER SYMBOL. For $m > 10$, u has an approximately NORMAL DISTRIBUTION with MEAN and VARIANCE

$$\mu_u = 1 + \frac{2mn}{m+n} \quad (22)$$

$$\sigma_u^2 = \frac{2mn(2mn-m-n)}{(m+n)^2(m+n-1)}. \quad (23)$$

Runge-Kutta Method

A method of numerically integrating ORDINARY DIFFERENTIAL EQUATIONS by using a trial step at the midpoint of an interval to cancel out lower-order error terms. The second-order formula is

$$k_1 = hf(s_n,\ y_n)$$

$$k_2 = hf\left(x_n + \tfrac{1}{2}h,\ y_n + \tfrac{1}{2}k_1\right)$$

$$y_{n+1} = y_n + k_2 + \mathcal{O}(h^3),$$

and the fourth-order formula is

$$k_1 = hf(s_n,\ y_n)$$

$$k_2 = hf\left(x_n + \tfrac{1}{2}h,\ y_n + \tfrac{1}{2}k_1\right)$$

$$k_3 = hf\left(x_n + \tfrac{1}{2}h,\ y_n + \tfrac{1}{2}k_2\right)$$

$$k_4 = hf(x_n + h,\ y_n + k_3)$$

$$y_{n+1} = y_n + \tfrac{1}{6}k_1 + \tfrac{1}{3}k_2 + \tfrac{1}{3}k_3 + \tfrac{1}{6}k_4 + \mathcal{O}(h^5).$$

(Press *et al.* 1992). This method is reasonably simple and robust and is a good general candidate for numerical solution of differential equations when combined with an intelligent adaptive step-size routine.

Runge's Theorem

Let $K \subseteq \mathbb{C}$ be compact, let f be analytic on a neighborhood of K, and let $P \subseteq \mathbb{C}^* \backslash K$ contain at least one point from each connected component of $\mathbb{C}^* \backslash K$. Then for any $\epsilon > 0$, there is a RATIONAL FUNCTION $r(z)$ with poles in P such that

$$\max_{z \in K} |f(z) - r(z)| < \epsilon$$

(Krantz 1999, p. 143).

A polynomial version can be obtained by taking $P = \{\infty\}$. Let $f(x)$ be an ANALYTIC FUNCTION which is REGULAR in the interior of a JORDAN CURVE C and continuous in the closed DOMAIN bounded by C. Then $f(x)$ can be approximated with arbitrary accuracy by POLYNOMIALS (Szego o 1975, p. 5; Krantz 1999, p. 144).

Runge-Walsh Theorem

RUNGE'S THEOREM

Run-Length Encoding

A specification of elements in a list as a list of pairs giving the element and number of times it occurs in a run. For example, given the list {1, 1, 1, 3, 3, 6, 6, 6, 2, 2, 2, 2, 3, 3, 1, 4, 4}, the run-length encoding is {{1, 3}, {3, 2}, {6, 3}, {2, 4}, {3, 2,}, {1, 1}, {4, 2}}. Run-length encoding can be implemented in *Mathematica* as

```
RunLengthEncode[x_List] := (Through[{First,
Length}[#1]] &) /@ Split[x]
```

See also LOOK AND SAY SEQUENCE, RUN

Running Average

MOVING AVERAGE

Running Knot

A KNOT which tightens around an object when strained but slackens when the strain is removed. Running knots are sometimes also known as slip knots or nooses.

References

Owen, P. *Knots.* Philadelphia, PA: Courage, p. 60, 1993.

Russell's Antinomy

Let R be the set of all sets which are not members of themselves. Then R is neither a member of itself nor not a member of itself. Symbolically, let $R = \{x : x \notin x\}$. Then $R \in R$ IFF $R \notin R$.

Bertrand Russell discovered this PARADOX and sent it in a letter to G. Frege just as Frege was completing *Grundlagen der Arithmetik.* This invalidated much of

the rigor of the work, and Frege was forced to add a note at the end stating, "A scientist can hardly meet with anything more undesirable than to have the foundation give way just as the work is finished. I was put in this position by a letter from Mr. Bertrand Russell when the work was nearly through the press."

Russell's Paradox

Russell's Antinomy

Russian Doll Prime

Prime String

Russian Multiplication

Also called "Ethiopian multiplication." To multiply two numbers a and b, write $a_0 \equiv a$ and $b_0 \equiv b$ in two columns. Under a_0, write $\lfloor a_0/2 \rfloor$, where $\lfloor x \rfloor$ is the floor function, and under b_0, write $2b_0$. Continue until $a_i = 1$. Then cross out any entries in the b column which are opposite an even number in the a column and add the b column. The result is the desired product. For example, for $a = 27$, $b = 35$

Russian Roulette

Russian roulette is a game of chance in which one or more of the six chambers of a gun are filled with bullets, the magazine is rotated at random, and the gun is fired. The shooter bets on whether the chamber which rotates into place will be loaded. If it is, he loses not only his bet but his life.

A modified version is considered by Blom *et al.* (1996) and Blom (1989). In this variant, the revolver is loaded with a single bullet, and two duelists alternately spin the chamber and fire at themselves until one is killed. The probability that the first duelist is killed is then 6/11.

Ruth-Aaron Pair

A pair of consecutive numbers $(n, n+1)$ such that the sums of the prime factors of n and $n+1$ are equal. They are so named because they were inspired by the pair (714, 715) corresponding to Hank Aaron's record-breaking 715th home run in 1974, breaking Babe Ruth's earlier record of 714 (Hoffman 1998, pp. 179–181). The first few ns giving Ruth-Aaron pairs are 5, 8, 15, 77, 125, 714, 948, ... (Sloane's A039752), corresponding to the sums 5, 6, 8, 18, 15, 29, 86, ... (Sloane's A054378).

Pomerance suspected there were an infinite number of such pairs, and this was almost immediately proved true by P. Erdos (Hoffman 1998, pp. 180–181).

Rutishauser's Rule

Let m and $m+h$ be two consecutive critical indices of f and let F be $(m+h)$-normal. If the polynomials $\tilde{p}_k^{(n)}$ are defined by

$$\tilde{p}_0^{(n)}(u) \equiv 1 \quad (1)$$

$$\tilde{p}_{k+1}^{(n)}(u) \equiv u\tilde{p}_k^{(n-1)}(u) - q_{m+k+1}^{(n)}\tilde{p}_k^{(n)}(u) \quad (2)$$

for $n = 0, 1, \ldots$ and $k = 0, \ldots, h-1$, then, under the hypothesis below, there exists an infinite set $\mathfrak{N}$ of positive integers such that

$$\lim_{\substack{n\to\infty \\ n\in\mathfrak{N}}} \tilde{p}_h^{(n)}(u) = \tilde{p}_h(u), \quad (3)$$

where

$$\tilde{p}_h(u) \equiv (u - u_{m+1})(u - u_{m+2})\cdots(u - u_{m+h}). \quad (4)$$

By hypothesis, if $m = 0$, the polynomials $\tilde{p}_k^{(n)}$ are identical to the Hadamard polynomials $p_L^{(n)}$, and if $m > 0$, the algorithm for constructing the $\tilde{p}_k^{(n)}$ is applied to the *qd* scheme suitably bounded by columns $e_m^{(n)}$ and $e_{m+h}^{(n)}$ (Henrici 1988, pp. 642–643).

Ryser Formula

A formula for the PERMANENT of a MATRIX

$$\operatorname{perm}(a_{ij}) = (-1)^n \sum_{s\subseteq\{1,\ \ldots,\ n\}} (-1)^{|s|} \prod_{i=1}^{n} \sum_{j\in s} a_{ij},$$

where the SUM is over all SUBSETS of $\{1, \ldots, n\}$, and $|s|$ is the number of elements in s. The formula can be optimized by picking the SUBSETS so that only a single element is changed at a time (which is precisely a GRAY CODE), reducing the number of additions from n^2 to n.

It turns out that the number of disks moved after the kth step in the TOWERS OF HANOI is the same as the element which needs to be added or deleted in the kth ADDEND of the Ryser formula (Gardner 1988, Vardi 1991, p. 111).

Saalschütz's Theorem

Mathematics:Calculus and Analysis:Special Functions:Hypergeometric Functions:Generalized Hypergeometric Functions

$$ {}_3F_2\left[\begin{matrix}-x,\ -y,\ -z \\ n+1,\ -x-y-z\end{matrix}\right] = \frac{\Gamma(n+1)\Gamma(x+y+n+1)}{\Gamma(x+n+1)\Gamma(y+n+1)} \times \frac{\Gamma(y+z+n+1)\Gamma(z+x+n+1)}{\Gamma(z+n+1)(x+y+z+n+1)}, \qquad (1) $$

where ${}_3F_2(a,\ b,\ c;\ d,\ e;\ z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION. It can be derived from the DOUGALL-RAMANUJAN IDENTITY and written in the symmetric form

$$ {}_3F_2(a,\ b,\ c;\ d,\ e;\ 1) = \frac{(d-a)_{|c|}(d-b)_{|c|}}{d_{|c|}(d-a-b)_{|c|}} \qquad (2) $$

for

$$ d+e=a+b+c+1 \qquad (3) $$

with c a NONPOSITIVE INTEGER and $(a)_n$ the POCHHAMMER SYMBOL (Bailey 1935, p. 9; Petkovsek *et al.* 1996; Koepf 1998, p. 32). If one of a, b, and c is nonpositive but it is not known which, an alternative formulation due to W. Gosper gives the form

$$ {}_3F_2(a,\ b,\ c;\ d,\ e;\ 1) = \frac{\Gamma(d)}{\Gamma(d-a)\Gamma(d-b)\Gamma(d-c)} \frac{\Gamma(e)}{\Gamma(e-a)(e-b)(e-c)} \times \frac{\pi^2}{\cos(\pi d)\cos(\pi e)+\cos(\pi a)\cos(\pi b)\cos(\pi c)}. \qquad (4) $$

which is symmetric in $(a,\ b,\ c)$ and $(d,\ e)$.

If instead

$$ a+b+c+2=d+e, \qquad (5) $$

then

$$ {}_3F_2(a,\ b,\ c;\ d,\ e;\ 2) \\ \pi^2 \frac{de-(a+1)(b+1)(c+1)+abc}{\cos(d\pi)\cos(e\pi)-\cos(a\pi)\cos(b\pi)\cos(c\pi)} \times \frac{\Gamma(d)}{\Gamma(d-a)\Gamma(d-b)\Gamma(d-c)} \frac{\Gamma(e)}{\Gamma(e-a)\Gamma(e-b)\Gamma(e-c)} \qquad (6) $$

(W. Gosper).

s-Additive Sequence

A generalization of an ULAM SEQUENCE in which each term is the SUM of two earlier terms in exactly s ways. $(s,\ t)$-additive sequences are a further generalization in which each term has exactly s representations as the SUM of t distinct earlier numbers. It is conjectured that 0-additive sequences ultimately have periodic differences of consecutive terms (Guy 1994, p. 233).

Saddle

A SURFACE possessing a SADDLE POINT.

See also HYPERBOLIC PARABOLOID, MONKEY SADDLE, SADDLE POINT (FUNCTION)

Saddle Point (Fixed Point)

HYPERBOLIC FIXED POINT (DIFFERENTIAL EQUATIONS), HYPERBOLIC FIXED POINT (MAP)

Saddle Point (Function)

A POINT of a FUNCTION or SURFACE which is a STATIONARY POINT but not an EXTREMUM. An example of a 1-D FUNCTION with a saddle point is $f(x) = x^3$, which has

$$f'(x) = 3x^2$$

$$f''(x) = 6x$$

$$f'''(x) = 6.$$

This function has a saddle point at $x_0 = 0$ by the EXTREMUM TEST since $f''(x_0) = 0$ and $f'''(x_0) = 6 \neq 0$. An example of a SURFACE with a saddle point is the MONKEY SADDLE.

Saddle Point (Game)

For a general two-player ZERO-SUM GAME,

$$\max_{i \leq m} \min_{j \leq n} a_{ij} \leq \min_{j \leq n} \max_{i \leq m} a_{ij}.$$

If the two are equal, then write

$$\max_{i \leq m} \min_{j \leq n} a_{ij} \leq \min_{j \leq n} \max_{i \leq m} a_{ij} \equiv v,$$

where v is called the VALUE of the GAME. In this case, there exist optimal strategies for the first and second players.

A NECESSARY and SUFFICIENT condition for a saddle point to exist is the presence of a PAYOFF MATRIX element which is both a minimum of its row and a maximum of its column. A GAME may have more than one saddle point, but all must have the same VALUE.

See also GAME, PAYOFF MATRIX, VALUE

Saint Petersburg Paradox

Consider a game, first proposed by Daniel Bernoulli, in which a player bets on how many tosses of a coin will be needed before it first turns up heads. The player pays a fixed amount initially, and then receives 2^n dollars if the coin comes up heads on the nth toss. The expectation value of the gain is then

$$\tfrac{1}{2}(2)+\tfrac{1}{4}(4)+\tfrac{1}{8}(8)+\ldots=1+1+1+\ldots=\infty$$

dollars, so any finite amount of money can be wagered and the player will still come out ahead on average.

Feller (1968) discusses a modified version of the game in which the player receives nothing if a trial takes more than a fixed number N of tosses. The classical theory of this modified game concluded that ∞ is a fair entrance fee, but Feller notes that "the modern student will hardly understand the mysterious discussions of this 'paradox'."

In another modified version of the game, the player bets \$2 that heads will turn up on the first throw, \$4 that heads will turn up on the second throw (if it did not turn up on the first), \$8 that heads will turn up on the third throw, etc. Then the expected *payoff* is

$$\tfrac{1}{2}(2)+\tfrac{1}{4}(4)+\tfrac{1}{8}(8)+\ldots=1+1+1+\ldots=\infty,$$

so the player can apparently be in the hole by any amount of money and still come out ahead in the end. This paradox can clearly be resolved by making the distinction between the amount of the final payoff and the net amount won in the game. It is misleading to consider the payoff without taking into account the amount lost on previous bets, as can be shown as follows. At the time the player first wins (say, on the nth toss), he will have lost

$$\sum_{k=1}^{n-1} 2^k = 2^n - 2$$

dollars. In this toss, however, he wins 2^n dollars. This means that the net gain for the player is a whopping \$2, no matter how many tosses it takes to finally win. As expected, the large payoff after a long run of tails is exactly balanced by the large amount that the player has to invest. In fact, by noting that the probability of winning on the nth toss is $1/2^n$, it can be seen that the probability distribution for the number of tosses needed to win is simply a geometric distribution with $p=1/2$.

Sal

Walsh Function

Salamin Formula

Brent-Salamin Formula

Salem Constants

Each point of a Pisot-Vijayaraghavan constant S is a limit point from both sides of a set T known as the Salem constants (Salem 1945). The Salem constants are algebraic integers >1 in which one or more of the conjugates is on the unit circle with the others inside (Le Lionnais 1983, p. 150). The smallest known Salem number was found by Lehmer (1933) as the largest real root of

$$x^{10}+x^9-x^7-x^6-x^5-x^4-x^3+x+1=0,$$

which is

$$\sigma_1 = 1.176280818\ldots$$

(Le Lionnais 1983, p. 35). Boyd (1977) found the following table of small Salem numbers, and suggested that σ_1, σ_2, σ_3, and σ_4 are the smallest Salem numbers. The NOTATION 1 1 0 −1 −1 −1 is short for 1 1 0 −1 −1 −1 −1 −1 0 1 1, the coefficients of the above polynomial.

Salmon's Theorem

There are at least two theorems known as Salmon's theorem. This first states that if P and S are two points, PX and SY are the perpendiculars from P and S to the POLARS of S and P, respectively, with respect to a CIRCLE with center O, then $OP/OS = PX/SY$ (Durell 1928).

The second Salmon's theorem states that, given a track bounded by two confocal ELLIPSES, if a ball is rolled so that its trajectory is tangent to the inner ELLIPSE, the ball's trajectory will be tangent to the inner ELLIPSE following all subsequent caroms as well.

Saltus

The word saltus has two different meanings: either a jump or an oscillation of a function.

Sample

See also POPULATION, SAMPLE PROPORTION, SAMPLE SIZE, SAMPLE SPACE, SAMPLE VARIANCE, SAMPLING

References

Kenney, J. F. and Keeping, E. S. "Populations and Samples." §7.1 in *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, pp. 90–91, 1962.

Sample Proportion

Let there be x successes out of n BERNOULLI TRIALS. The sample proportion is the fraction of samples which were successes, so

$$\hat{p} = \frac{x}{n}. \tag{1}$$

For large n, $\hat{p}$ has an approximately NORMAL DISTRIBUTION. Let RE be the RELATIVE ERROR and SE the STANDARD ERROR, then

$$\langle p \rangle = p \tag{2}$$

$$\mathrm{SE}(\hat{p}) \equiv \sigma(\hat{p}) = \sqrt{\frac{p(1-p)}{n}} \tag{3}$$

$$\mathrm{RE}(\hat{p}) = \sqrt{\frac{2\hat{p}(1-\hat{p})}{n}}\,\mathrm{erf}^{-1}(\mathrm{CI}), \tag{4}$$

where CI is the CONFIDENCE INTERVAL and erf x is the ERF function. The number of tries needed to determine p with RELATIVE ERROR RE and CONFIDENCE

INTERVAL CI is

$$n = \frac{2\left[\operatorname{erf}^{-1}(\mathrm{CI})\right]^2 \hat{p}(1-\hat{p})}{(\mathrm{RE})^2}. \quad (5)$$

Sample Size

See also SAMPLE, SAMPLE VARIANCE

Sample Space

Informally, the sample space for a given set of events is the set of all possible values the events may assume. Formally, the set of possible events for a given variate forms a SIGMA ALGEBRA, and sample space is defined as the largest set in the SIGMA ALGEBRA.

See also PROBABILITY SPACE, RANDOM VARIABLE, SAMPLE, SIGMA ALGEBRA, STATE SPACE

Sample Variance

To estimate the population VARIANCE σ^2 from a sample of N elements with a priori *unknown* MEAN (i.e., the MEAN is estimated from the sample itself), we need an unbiased ESTIMATOR for σ^2. This ESTIMATOR is given by K-STATISTIC k_2, where

$$k_2 = \frac{N}{N-1} m_2 \quad (1)$$

and $m_2 \equiv s^2$ is the sample variance

$$s^2 \equiv \frac{1}{N} \sum_{i=1}^{N} (x_i - \bar{x})^2. \quad (2)$$

Note that some authors prefer the definition

$$s'^2 \equiv \frac{1}{N-1} \sum_{i=1}^{N} (x_i - \bar{x})^2, \quad (3)$$

since this makes the sample variance an UNBIASED ESTIMATOR for the population variance.

Also note that, in general, $\sqrt{\hat{\sigma}^2}$ in *not* an UNBIASED ESTIMATOR of σ even if $\hat{\sigma}^2$ is an UNBIASED ESTIMATOR for σ^2).

See also K-STATISTIC, SAMPLE, UNBIASED ESTIMATOR, VARIANCE

Sampling

The selection and implementation of statistical observations in order to estimate properties of an underlying population. Sampling is a vital part of modern polling, market research, and manufacturing, and its proper use is vital in the functioning of modern economies.

For infinite precision sampling of a band-limited signal at the NYQUIST FREQUENCY, the SIGNAL-TO-NOISE RATIO after N_q samples is

$$\mathrm{SNR} = \frac{\langle r_\infty \rangle}{\sigma_\infty} = \frac{\rho\sigma^2}{\sigma^2 N_q^{-1/2}\sqrt{1+\rho^2}} = \frac{\rho}{\sqrt{1+\rho^2}}\sqrt{N_q}, \quad (1)$$

where ρ is the normalized CROSS-CORRELATION COEFFICIENT

$$\rho \equiv \frac{\langle x(t) \rangle \langle y(t) \rangle}{\sqrt{\langle x^2(t) \rangle \langle y^2(t) \rangle}}. \quad (2)$$

For $\rho \ll 1$,

$$\mathrm{SNR} \approx \rho\sqrt{N_q}. \quad (3)$$

The identical result is obtained for oversampling. For undersampling, the SIGNAL-TO-NOISE RATIO decreases (Thompson *et al.* 1986).

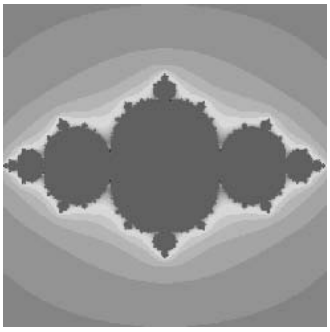
Sampling Function

SHAH FUNCTION

Sampling Theorem



In order for a band-limited (i.e., one with a zero POWER SPECTRUM for frequencies $\nu > B$) baseband ($\nu > 0$) signal to be reconstructed fully, it must be sampled at a rate $\nu \geq 2B$. A signal sampled at $\nu = 2B$ is said to be NYQUIST SAMPLED, and $\nu = 2B$ is called the NYQUIST FREQUENCY. No information is lost if a signal is sampled at the NYQUIST FREQUENCY, and no additional information is gained by sampling faster than this rate.

Sandwich Theorem

The LOVÁSZ NUMBER $\vartheta(G)$ of a GRAPH G satisfies

$$\omega(G) \le \vartheta(\bar{G}) \le \chi(G).$$

where $\omega(G)$ is the CLIQUE NUMBER and χ is the minimum number of colors needed to color the VERTICES of G. $\vartheta(G)$ can be computed efficiently despite the fact that the computation of the two numbers it lies between is an NP-HARD PROBLEM.

The SQUEEZING THEOREM is also sometimes known as the sandwich theorem.

Sarkovskii's Theorem

Order the NATURAL NUMBERS as follows:

$$\begin{aligned}&3 \prec 5 \prec 7 \prec 9 \prec 11 \prec 13 \prec 15 \prec \ldots \prec 2\cdot 3 \prec 2\cdot 5 \prec 2\cdot 7\\ &\prec 2\cdot 9 \prec \ldots \prec 2\cdot 2\cdot 3 \prec 2\cdot 2\cdot 5 \prec 2\cdot 2\cdot 7\\ &\prec 2\cdot 2\cdot 9 \prec \ldots \prec 2\cdot 2\cdot 2\cdot 3 \prec \ldots \prec 2^5 \prec 2^4 \prec 2^3 \prec 2^2\\ &\prec 2 \prec 1.\end{aligned}$$

Now let F be a CONTINUOUS FUNCTION from the REALS to the REALS and suppose $p \prec q$ in the above ordering. Then if F has a point of LEAST PERIOD p, then F also has a point of LEAST PERIOD q.

A special case of this general result, also known as Sarkovskii's theorem, states that if a CONTINUOUS REAL function has a PERIODIC POINT with period 3, then there is a PERIODIC POINT of period n for every INTEGER n.

A converse to Sarkovskii's theorem says that if $p \prec q$ in the above ordering, then we can find a CONTINUOUS FUNCTION which has a point of LEAST PERIOD q, but does not have any points of LEAST PERIOD p (Elaydi 1996). For example, there is a CONTINUOUS FUNCTION with no points of LEAST PERIOD 3 but having points of all other LEAST PERIODS.

Sárközy's Theorem

A partial solution to the ERDOS SQUAREFREE CONJECTURE which states that the BINOMIAL COEFFICIENT $\binom{2n}{n}$ is never SQUAREFREE for all sufficiently large $n \geq n_0$. Sárkozy (1985) showed that if $s(n)$ is the square part of the BINOMIAL COEFFICIENT $\binom{2n}{n}$, then

$$\ln s(n) \sim \left(\sqrt{2}-2\right)\zeta\left(\tfrac{1}{2}\right)\sqrt{n}.$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION. An upper bound on n_0 of $2^{8,000}$ has been obtained.

SAS Theorem

Specifying two sides and the ANGLE between them uniquely determines a TRIANGLE. Let c be the base length and h be the height. Then the AREA is

$$K = \tfrac{1}{2} ch = \tfrac{1}{2} ac \sin B. \tag{1}$$

The length of the third side is given by the LAW OF COSINES,

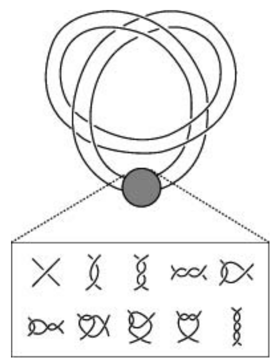
$$b^2 = a^2 + c^2 - 2ac \cos B.$$

so

$$b = \sqrt{a^2 + c^2 - 2ac \cos B}. \tag{2}$$

Using the LAW OF SINES

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \tag{3}$$



then gives the two other ANGLES as

$$A = \sin^{-1}\left(\frac{a \sin B}{\sqrt{a^2 + c^2 - 2ac \cos B}}\right) \tag{4}$$

$$C = \sin^{-1}\left(\frac{c \sin B}{\sqrt{a^2 + c^2 - 2ac \cos B}}\right) \tag{5}$$

See also AAA THEOREM, AAS THEOREM, ASA THEOREM, ASS THEOREM, SSS THEOREM, TRIANGLE

Satellite Knot

Let K_1 be a knot inside a TORUS, and knot the TORUS in the shape of a second knot (called the COMPANION KNOT) K_2, with certain additional mild restrictions to avoid trivial cases. Then the new knot resulting from K_1 is called the satellite knot K_3. All satellite knots are PRIME (Hoste *et al.* 1998). The illustration above illustrates a satellite knot of the TREFOIL KNOT, which is the form all satellite knots of 16 or fewer crossings take (Hoste *et al.* 1998). Satellites of the trefoil share the trefoil's chirality, and all have wrapping number 2.

Any satellite knot having wrapping number > 2 must have at least 27 crossings, and any satellite of the FIGURE EIGHT KNOT must have at least 17 crossings (Hoste *et al.* 1998). The numbers of satellite knots with n crossings are 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 2, 6, 10, ... (Sloane's A051765), so the satellite knot of minimal crossing number occurs for 13 crossings.

The only KNOTS which are not HYPERBOLIC KNOTS are TORUS KNOTS and satellite knots (including COMPOSITE KNOTS). No satellite knot is an ALMOST ALTERNATING KNOT. If a COMPANION KNOT has crossing number k and the satellite ravels m times longitudinally around the solid torus, then it is conjectured that the satellite cannot be projected with fewer than km^2 crossings (Hoste *et al.* 1998).

Satisfaction

Let $\mathbb{A}$ be a RELATIONAL SYSTEM, and let L be a language which is appropriate for $\mathbb{A}$. Let ϕ be a well-formed formula of L, and let s be a valuation in

$\mathbb{A}$. Then $\mathbb{A} \models_s \phi$ is written provided that one of the following holds:

1. ϕ is of the form $x = y$, for some variables x and y of L, and s maps x and y to the same element of the structure $\mathbb{A}$.
2. ϕ is of the form $Rx_1 \cdots x_n$, for some n-ary predicate symbol R of the language L, and some variables $x_1 \cdots x_n$ of L, and $\{s(x_1), \ldots, s(x_n)\}$ is a member of $R^{\mathbb{A}}$.
3. ϕ is of the form $(\psi \wedge \gamma)$, for some formulas ψ and γ of L such that $\mathbb{A} \models_s \psi$ and $\mathbb{A} \models_s \gamma$.
4. ϕ is of the form $((\exists x)\psi)$, and there is an element a of $\mathbb{A}$ such that $\mathbb{A} \models_{s(x|a)} \psi$.

In this case, $\mathbb{A}$ is said to satisfy ϕ with the valuation s.

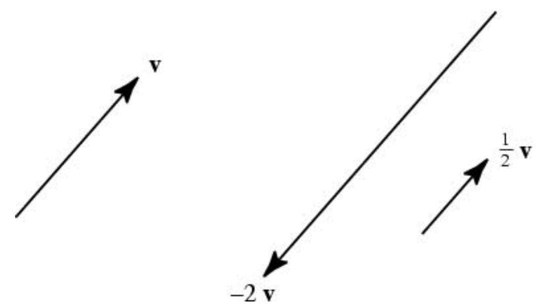
Scalar Field

A MAP $f : \mathbb{R}^n \mapsto \mathbb{R}$ which assigns each $\mathbf{x}$ a SCALAR FUNCTION $f(\mathbf{x})$.

See also VECTOR FIELD

References



Morse, P. M. and Feshbach, H. "Scalar Fields." §1.1 in *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, pp. 4–8, 1953.

Scalar Function

A function $f(x_1, \ldots, x_n)$ of one or more variables whose RANGE is one-dimensional, as compared to a VECTOR FUNCTION, whose RANGE is three-dimensional (or, in general, n-dimensional).

See also COMPLEX FUNCTION, REAL FUNCTION, VECTOR FUNCTION

Scalar Multiplication

Scalar multiplication refers to the multiplication of a VECTOR by a constant s, producing a vector in the same (for $s > 0$) or opposite (for $s < 0$) direction but of different length. Scalar multiplication is indicated in *Mathematica* by placing a scalar next to a vector (with or without an optional asterisk), $s\{a1, a2, \ldots, an\}$.

See also MULTIPLICATION, VECTOR, VECTOR ADDITION, VECTOR MULTIPLICATION

Scalar Potential

A conservative VECTOR FIELD (for which the CURL $\nabla \times \mathbf{F} = \mathbf{0}$) may be assigned a scalar potential

$$\phi(x, y, z) - \phi(0, 0, 0) \equiv -\int_C \mathbf{F} \cdot d\mathbf{s}$$

$$= -\int_{(0,0,0)}^{(x,0,0)} F_1(t, 0, 0)\,dt + \int_{(x,0,0)}^{(x,y,0)} F_2(x, t, 0)\,dt$$

$$+ \int_{(x,y,0)}^{x,y,z} F_3(x, y, t)\,dt.$$

where $\int_C \mathbf{F} \cdot d\mathbf{s}$ is a LINE INTEGRAL.

See also LINE INTEGRAL, POTENTIAL FUNCTION, VECTOR POTENTIAL

Scalar Product

DOT PRODUCT

Scalar Triple Product

The scalar triple product of three VECTORS $\mathbf{A}$, $\mathbf{B}$, and $\mathbf{C}$ is denoted $[\mathbf{A}, \mathbf{B}, \mathbf{C}]$ and defined by

$$[\mathbf{A}, \mathbf{B}, \mathbf{C}] \equiv \mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) \quad (1)$$

$$= \mathbf{B} \cdot (\mathbf{C} \times \mathbf{A}) \quad (2)$$

$$= \mathbf{C} \cdot (\mathbf{A} \times \mathbf{B}) \quad (3)$$

$$= \det(\mathbf{A}(\mathbf{BC})) \quad (4)$$

$$= \begin{vmatrix} A_1 & A_2 & A_3 \\ A_2 & C_2 & B_3 \\ A_3 & C_2 & C_3 \end{vmatrix} \quad (5)$$

where $\mathbf{A} \cdot \mathbf{B}$ denotes a DOT PRODUCT, $\mathbf{A} \times \mathbf{B}$ denotes a CROSS PRODUCT, $\det(\mathsf{A}) = |\mathsf{A}|$ denotes a DETERMINANT,

and A_i, B_i, and C_i are components of the vectors **A**, **B**, and **C**, respectively. The scalar triple product is a PSEUDOSCALAR (i.e., it reverses sign under inversion). The scalar triple product can also be written in terms of the PERMUTATION SYMBOL ϵ_{ijk} as

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \epsilon_{ijk} A^i B^j C^k. \tag{6}$$

where EINSTEIN SUMMATION has been used to sum over repeated indices.

Additional identities involving the scalar triple product are

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \mathbf{B} \cdot (\mathbf{C} \times \mathbf{A}) = \mathbf{C} \cdot (\mathbf{A} \times \mathbf{B}) \tag{7}$$

$$[\mathbf{A}, \mathbf{B}, \mathbf{C}]\mathbf{D} = [\mathbf{D}, \mathbf{B}, \mathbf{C}]\mathbf{A} + [\mathbf{A}, \mathbf{D}, \mathbf{C}]\mathbf{B} + [\mathbf{A}, \mathbf{B}, \mathbf{D}]\mathbf{C} \tag{8}$$

$$[\mathbf{q}, \mathbf{q}', \mathbf{q}''][\mathbf{r}, \mathbf{r}', \mathbf{r}''] = \begin{vmatrix} \mathbf{q} \cdot \mathbf{r} & \mathbf{q} \cdot \mathbf{r}' & \mathbf{q} \cdot \mathbf{r}'' \\ \mathbf{q}' \cdot \mathbf{r} & \mathbf{q}' \cdot \mathbf{r}' & \mathbf{q}' \cdot \mathbf{r}'' \\ \mathbf{q}'' \cdot \mathbf{r} & \mathbf{q}'' \cdot \mathbf{r}' & \mathbf{q}'' \cdot \mathbf{r}'' \end{vmatrix}. \tag{9}$$

The VOLUME of a PARALLELEPIPED whose sides are given by the vectors **A**, **B**, and **C** is given by the ABSOLUTE VALUE of the scalar triple product

$$V_{\text{parallelepiped}} = .|\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C})|. \tag{10}$$

Scale

BASE (NUMBER)

Scale Factor

For a diagonal METRIC TENSOR $g_{ij} = g_{ii}\delta_{ij}$, where δ_{ij} is the KRONECKER DELTA, the scale factor is defined by

$$h_i \equiv \sqrt{g_{ii}}. \tag{1}$$

The LINE ELEMENT (first FUNDAMENTAL FORM) is then given by

$$ds^2 = g_{11}\,dx_{11}^2 + g_{22}\,dx_{22}^2 + g_{33}\,dx_{33}^2 \tag{2}$$

$$= h_1^2\,dx_{11}^2 + h_2^2\,dx_{22}^2 + h_3^2\,dx_{33}^2. \tag{3}$$

The scale factor appears in vector derivatives of coordinates in CURVILINEAR COORDINATES.

See also CURVILINEAR COORDINATES, FUNDAMENTAL FORMS, LINE ELEMENT

Scale Invariance

SELF-SIMILARITY

Scalene Triangle

A TRIANGLE with three unequal sides.

See also ACUTE TRIANGLE, EQUILATERAL TRIANGLE, ISOSCELES TRIANGLE, OBTUSE TRIANGLE, TRIANGLE

Scaling

Increasing a plane figure's linear dimensions by a scale factor s increases the PERIMETER $p' \to sp$ and the AREA $A' \to s^2A$.

Schanuel's Conjecture

Let $\lambda_1, ..., \lambda_n \in \mathbb{C}$ be linearly independent over the RATIONALS $\mathbb{Q}$, then

$$\mathbb{Q}(\lambda_1, \ldots, \lambda_n, e^{\lambda_1}, \ldots, e^{\lambda_n})$$

has TRANSCENDENCE degree at least n over $\mathbb{Q}$. Schanuel's conjecture implies the LINDEMANN-WEIERSTRASS THEOREM and GELFOND'S THEOREM. If the conjecture is true, then it follows that e and π are ALGEBRAICALLY INDEPENDENT. Mcintyre (1991) proved that the truth of Schanuel's conjecture also guarantees that there are no unexpected exponential-algebraic relations on the INTEGERS $\mathbb{Z}$ (Marker 1996).

At present, a proof of Schanuel's conjecture seems out of reach (Chow 1999).

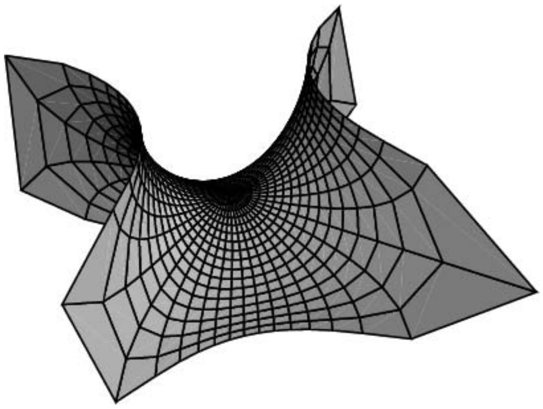
Scherk's Minimal Surfaces



Scherk's two MINIMAL SURFACES were discovered by Scherk in 1834. They were the first new surfaces discovered since Meusnier in 1776. Beautiful images of wood sculptures of Scherk surfaces are illustrated by Séquin.

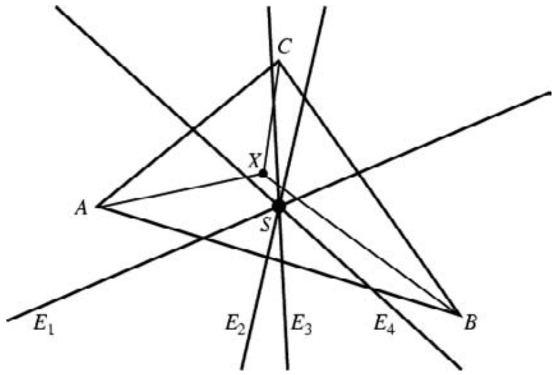
Scherk's first surface is doubly periodic and is defined by the implicit equation

$$e^z \cos y = \cos x, \tag{1}$$

(Osserman 1986, Wells 1991, von Seggern 1993). It has been observed to form in layers of block copolymers (Peterson 1988).

Scherk's second surface can be written parametrically as

$$x = 2\Re\left[\ln\left(1 + re^{i\theta}\right) - \ln\left(1 - re^{i\theta}\right)\right] \quad (2)$$



$$y = \Re\left[4i \tan^{-1}\left(re^{i\theta}\right)\right] \quad (3)$$

$$z = \Re\left\{2i\left(-\ln\left[1 - r^2e^{2i\theta}\right] + \ln\left[1 + r^2e^{2i\theta}\right]\right)\right\} \quad (4)$$

for $\theta \in [0,\ 2\pi)$, and $r \in (0,\ 1)$.

Schinzel Circle

A CIRCLE having a given number of LATTICE POINTS on its CIRCUMFERENCE. The Schinzel circle having n lattice points is given by the equation

$$\begin{cases} \left(x - \frac{1}{2}\right)^2 + y^2 = \frac{1}{4}\,5^{k-1} & \text{for } n = 2k \text{ even} \\ \left(x - \frac{1}{3}\right)^2 + y^2 = \frac{1}{9}\,5^{2k} & \text{for } n = 2k+1 \text{ odd.} \end{cases}$$

Note that these solutions do not necessarily have the smallest possible RADIUS. For example, while the Schinzel circle centered at (1/3, 0) and with radius 625/3 has nine lattice points on its circumference, so does the circle centered at (1/3, 0) with radius 65/3.

Schinzel's Theorem

For every POSITIVE INTEGER n, there exists a CIRCLE in the plane having exactly n LATTICE POINTS on its CIRCUMFERENCE. The theorem is based on the number $r(n)$ of integral solutions (x, y) to the equation

$$x^2+y^2=n, \qquad (1)$$

given by

$$r(n)=4(d_1-d_3), \qquad (2)$$

where d_1 is the number of divisors of n OF THE FORM $4k+1$ and d_3 is the number of divisors OF THE FORM $4k+3$. It explicitly identifies such circles (the SCHINZEL CIRCLES) as

$$\begin{cases} \left(x-\frac{1}{2}\right)^2+y^2=\frac{1}{4}\,5^{k-1} & \text{for } n=2k \\ \left(x-\frac{1}{3}\right)^2+y^2=\frac{1}{9}\,5^{2k} & \text{for } n=2k+1. \end{cases} \qquad (3)$$

Note, however, that these solutions do not necessarily have the smallest possible radius.

Schläfli Double Sixes

DOUBLE SIXES

Schläfli Function

The function giving the VOLUME of the spherical quadrectangular TETRAHEDRON:

$$V=\frac{\pi^2}{8}\,f\left(\frac{\pi}{p},\,\frac{\pi}{q},\,\frac{\pi}{r}\right),$$

where

$$\tfrac{1}{2}\,\pi^2 f\left(\tfrac{\pi}{2}-x,\,y,\,\tfrac{\pi}{2}-z\right)=\sum_{m=1}^{\infty}\left(\frac{D-\sin x\sin z}{D+\sin x\sin z}\right)^m$$

$$\times\frac{\cos(2mx)-\cos(2my)+\cos(2mz)-1}{m^2}-x^2-y^2-z^2,$$

and

$$D\equiv\sqrt{\cos^2 x\cos^2 z-\cos^2 y}.$$

See also TETRAHEDRON

Schläfli Integral

A definition of a function using a CONTOUR INTEGRAL. Schläfli integrals may be converted into RODRIGUES FORMULAS.

See also RODRIGUES FORMULA

Schläfli Polynomial

A polynomial given in terms of the NEUMANN POLYNOMIALS $O_n(x)$ by

$$S_n(x)=\frac{2xO_n(x)-2\cos^2\left(\frac{1}{2}\,n\pi\right)}{n}.$$

Schläfli Symbol

A symbol of the form $\{p, q, r, \ldots\}$ used to describe regular polygons, polyhedra, and their higher-dimensional counterparts.

The symbol $\{p\}$ denotes a REGULAR POLYGON. The symbol $\{p, q\}$ denotes a TESSELLATION of regular p-gons, with q of them surrounding each VERTEX. The Schläfli symbol can also be used to describe PLATONIC SOLIDS and KEPLER-POINSOT SOLIDS, and a generalized version describes QUASIREGULAR POLYHEDRA and ARCHIMEDEAN SOLIDS. Higher dimensional symbols can be used to describe the REGULAR POLYCHORA and POLYTOPES.

The symbol has the particularly nice property that its reversal gives the symbol of the DUAL POLYHEDRON. The following tables gives Schläfli symbols for several polytopes.

POLYHEDRON	Symbol
GREAT STELLATED DODECAHEDRON	$\left\{\frac{5}{2}, 3\right\}$
SMALL STELLATED DODECAHEDRON	$\left\{\frac{5}{2}, 5\right\}$
GREAT ICOSAHEDRON	$\left\{3, \frac{5}{2}\right\}$
TETRAHEDRON	$\{3, 3\}$
PENTATOPE	$\{3, 3, 3\}$
n-simplex	$\{\underbrace{3, \ldots, 3}_{n-1}\}$
16-CELL	$\{3, 3, 4\}$
n-cross polytope	$\{\underbrace{3, \ldots, 3}_{n-2}, 4\}$
600-CELL	$\{3, 3, 5\}$
OCTAHEDRON	$\{3, 4\}$
24-CELL	$\{3, 4, 3\}$
ICOSAHEDRON	$\{3, 5\}$
CUBE	$\{4, 3\}$
TESSERACT	$\{4, 3, 3\}$
n-hypercube	$\{4, \underbrace{3, \ldots, 3}_{n-2}\}$
GREAT DODECAHEDRON	$\left\{5, \frac{5}{2}\right\}$
DODECAHEDRON	$\{5, 3\}$
120-CELL	$\{5, 3, 3\}$

See also ARCHIMEDEAN SOLID, PLATONIC SOLID, QUASIREGULAR POLYHEDRON, REGULAR POLYCHORON, REGULAR POLYGON, TESSELLATION

Schläfli's Formula

For $\Re[z] > 0$,

$$J_\nu(z) = \frac{1}{\pi}\int_0^{\pi/2} \cos(z \sin t - \nu t)\, dt - \frac{\sin(\nu\pi)}{\pi}\int_0^\infty e^{-z \sinh t} e^{-\nu t}\, dt,$$

where $J_\nu(z)$ is a BESSEL FUNCTION OF THE FIRST KIND.

References

Schlicht Function

An ANALYTIC FUNCTION f on the UNIT DISK is called schlicht if

1. f is ONE-TO-ONE,
2. $f(0)=0$, and
3. $f'(0)=1$,

in which case it is written $f \in S$. Schlicht functions have power series of the form

$$f(z)=Z+\sum_{j=2}^{\infty} a_j z^j.$$

Schlömilch Remainder

A TAYLOR SERIES remainder formula that gives after n terms of the series

$$R_n=\frac{f^{(n+1)}(x^*)}{n!p}(x-x^*)^{n+1-p}(x-x_0)^{n+1}$$

for $x^* \in (x_0, x)$ and any $p>0$ (Blumenthal 1926, Beesack 1966), which Blumenthal (1926) ascribes to Roche (1858). The choices $p=n+1$ and $p=1$ give the LAGRANGE and CAUCHY REMAINDERS, respectively (Beesack 1966).

See also CAUCHY REMAINDER, LAGRANGE REMAINDER

Schlömilch's Function

Mathematics:Calculus and Analysis:Special Functions:Hypergeometric Functions:Confluent Hypergeometric Functions

$$S(v, z) \equiv \int_0^{\infty} (1+t)^{-v} e^{-zt}\, dt = z^{v-1} e^z \int_z^{\infty} u^{-v} e^{-u}\, du$$
$$= z^{v/2-1} e^{z/2} W_{-v/2,(1-v)/2}(z),$$

where $W_{k,m}(z)$ is the WHITTAKER FUNCTION.

Schlömilch's Series

A FOURIER SERIES-like expansion of a twice continuously differentiable function

$$f(x)=\tfrac{1}{2}a_0+\sum_{n=1}^{\infty} a_n J_0(nx)$$

for $0<x<\pi$, where $J_0(x)$ is a zeroth order BESSEL FUNCTION OF THE FIRST KIND and

$$a_0 \equiv 2f(0)+\frac{2}{\pi}\int_0^{\pi} du \int_0^{\pi/2} f'(u \sin\phi)\, d\phi$$

$$a_n \equiv \frac{2}{\pi}\int_0^{\pi} du \int_0^{\pi/2} uf'(u \sin\phi)\cos(n\pi)\, d\phi.$$

A special case gives the amazing identity

$$1=J_0(z)+2\sum_{n=1}^{\infty} J_{2n}(z)=[J_0(z)]^2+2\sum_{n=1}^{\infty}[J_n(z)]^2.$$

Schmitt-Conway Biprism

A CONVEX POLYHEDRON which is SPACE-FILLING, but only aperiodically, was found by Conway in 1993.

See also CONVEX POLYHEDRON, SPACE-FILLING POLYHEDRON

Schnirelmann Constant

The constant s_0 in SCHNIRELMANN'S THEOREM such that every INTEGER >1 is a sum of at most s_0 PRIMES. Of course, by VINOGRADOV'S THEOREM, it is known that 4 primes suffice for all *sufficiently large* numbers, but this constant gives a sufficient number for *all* numbers. The best current estimate is $s_0=7$ (Ramaré 1995), and a summary of progress on upper bounds for s_0 is summarized in the following table.

s_0	author
7	Ramaré (1995)
19	Riesel and Vaughan (1983)
26	Deshouillers (1977)
27	Vaughan (1977)
55	Klimov (1975)
115	Klimov *et al.* (1972)
159	Deshouillers (1973)

Schnirelmann's Theorem

This entry contributed by KEVIN O'BRYANT

There exists a POSITIVE INTEGER s such that every SUFFICIENTLY LARGE INTEGER is the sum of at most s PRIMES. It follows that there exists a POSITIVE INTEGER $s_0 \geq s$ such that every INTEGER >1 is a sum of at most s_0 PRIMES. The smallest proven value of s_0 is known as the SCHNIRELMANN CONSTANT.

Schnirelmann's theorem can be proved using MANN'S THEOREM, although Schnirelmann used the weaker inequality

$$\sigma(A \oplus B) \geq \sigma(A) + \sigma(B) - \sigma(A)\sigma(B),$$

where $0 \in A \cap B$, $A \oplus B = \{a + b : a \in A,\ b \in B\}$, and σ is the SCHNIRELMANN DENSITY. Let $P = \{0, 1, 2, 3, 5, \ldots\}$ be the set of primes, together with 0 and 1, and let $Q = P \oplus P$. Using a sophisticated version of the INCLUSION-EXCLUSION PRINCIPLE, Schnirelmann showed that although $\sigma(P) = 0$, $\sigma(Q) > 0$. By repeated applications of MANN'S THEOREM, the sum of k copies of Q satisfies $\sigma(Q + Q + \ldots + Q) \geq \min\{1, k\sigma(Q)\}$. Thus, if $k > 1/\sigma(Q)$, the sum of k copies of Q has SCHNIRELMANN DENSITY 1, and so contains all positive integers.

Schönflies Theorem

If J is a simple closed curve in $\mathbb{R}^2$, the closure of one of the components of $\mathbb{R}^2 - J$ is HOMEOMORPHIC with the unit 2-BALL. This theorem may be proved using the RIEMANN MAPPING THEOREM, but the easiest proof is via MORSE THEORY.

The generalization to n-D is called MAZUR'S THEOREM. It follows from the Schönflies theorem that any two KNOTS of $\mathbb{S}^1$ in $\mathbb{S}^2$ or $\mathbb{R}^2$ are equivalent.

KIRKMAN'S SCHOOLGIRL PROBLEM

Schoute Coaxal System

The CIRCUMCIRCLE, BROCARD CIRCLE, LEMOINE LINE, and ISODYNAMIC POINTS belong to a COAXAL SYSTEM orthogonal to the APOLLONIUS CIRCLES, called the Schoute coaxal system. In general, there are 12 points whose PEDAL TRIANGLES with regard to a given TRIANGLE have a given form. They lie six by six on two CIRCLES of the Schoute coaxal system.

Schröder Number

The Schröder number S_n is the number of LATTICE PATHS in the Cartesian plane that start at (0, 0), end at (n, n), contain no points above the line $y=x$, and are composed only of steps (0, 1), (1, 0), and (1, 1), i.e., →, ↑, and ↗. The diagrams illustrating the paths generating S_1, S_2, and S_3 are illustrated above. The numbers S_n are given by the RECURRENCE RELATION

$$S_n = S_{n-1} + \sum_{k=0}^{n-1} S_k S_{n-1-k},$$

where $S_0 = 1$, and the first few are 2, 6, 22, 90, ... (Sloane's A006318). The Schröder Numbers bear the same relation to the DELANNOY NUMBERS as the CATALAN NUMBERS do to the BINOMIAL COEFFICIENTS.

Schröder-Bernstein Theorem

The Schröder-Bernstein theorem for numbers states that if

$$n \leq m \leq n.$$

then $m=n$ For SETS, the theorem states that if there are INJECTIONS of the SET A into the SET B and of B into A, then there is a BIJECTIVE correspondence between A and B (i.e., they are EQUIPOLLENT).

See also BIJECTION, CARDINAL COMPARISON, EQUIPOLLENT, INJECTION, TRICHOTOMY LAW

Schröder's Equation

The functional equation

$$\phi(f(x)) = s\phi(x).$$

with $s \neq 0,\ 1$.

References

Kuczma, M. Ch. 6 in *Functional Equations in a Single Variable.* Warsaw, Poland: Polska Akademia Nauk, 1968.

Schröder's Method

Two families of equations used to find roots of nonlinear functions of a single variable. The "B" family is more robust and can be used in the neighborhood of degenerate multiple roots while still providing a guaranteed convergence rate. Almost all other root-finding methods can be considered as special cases of Schröder's method. Householder humorously claimed that papers on root-finding could be evaluated quickly by looking for a citation of Schröder's paper; if the reference were missing, the paper probably consisted of a rediscovery of a result due to Schröder (Stewart 1993).

One version of the "A" method is obtained by applying NEWTON'S METHOD to f/f',

$$x_{n+1} = x_n - \frac{f(x_n)f'(x_n)}{[f'(x_n)]^2 - f(x_n)f''(x_n)}$$

(Scavo and Thoo 1995).

Schrödinger Equation

The Schrödinger equation describes the motion of particles in nonrelativistic quantum mechanics, and was first written down by Erwin Schrödinger. The time-dependent Schrödinger equation is given by

$$ih\,\frac{\partial\psi(x,\ y,\ z,\ t)}{\partial t}$$

$$\left[-\frac{h^2}{2m}\,\nabla^2+V(x)\right]\Psi(x,\ y,\ z,\ t)=\bar{H}\Psi(x,\ y,\ z,\ t), \quad (1)$$

where h is h-bar , Ψ is the time-dependent wavefunction, m is the mass of a particle, ∇^2 is the LAPLACIAN, V is the potential, and $\bar{H}$ is the Hamiltonian operator. The time-independent Schrödinger equation is

$$\left[-\frac{h^2}{2m}\,\nabla^2+V(x)\right]\psi(x,\ y,\ z,\ t)=E\psi(x,\ y,\ z,\ t). \quad (2)$$

The one-dimensional versions of these equations are then

$$ih\,\frac{\partial\Psi(x,\ t)}{\partial t}=\left[-\frac{h^2}{2m}\,\frac{\partial^2}{\partial x^2}+V(x)\right]\Psi(x,\ t)$$
$$=\bar{H}\Psi(x,\ t), \quad (3)$$

and

$$\left[-\frac{h^2}{2m}\,\frac{d^2}{dx^2}+V(x)\right]\psi(x)=E\psi(x). \quad (4)$$

The logarithmic Schrödinger equation is given by

$$iu_t+\nabla^2 u+u\ \ln|u|^2=0 \quad (5)$$

(Cazenave 1983; Zwillinger 1997, p. 134), the nonlinear Schrödinger equation by

$$iu_t+u_{xx}\pm 2|u|^2u=0 \quad (6)$$

(Calogero and Degasperis 1982, p. 56; Tabor 1989, p. 309; Zwillinger 1997, p. 134) or

$$iu_t+u_{xx}+au+b|u|^2u=0 \quad (7)$$

(Infeld and Rowlands 2000, p. 126), and the derivative nonlinear Schrödinger equation by

$$iu_t+u_{xx}\pm i(|u|^2u)_x=0 \quad (8)$$

(Calogero and Degasperis 1982, p. 56; Zwillinger 1997, p. 134).

Schur Matrix

The $p \times p$ SQUARE MATRIX formed by setting $s_{ij} = \xi^{ij}$, where ξ is a pth ROOT OF UNITY. The Schur matrix has a particularly simple DETERMINANT given by

$$\det \mathsf{S} = \epsilon_p p^{p/2},$$

where p is an ODD PRIME and

$$\epsilon_p \equiv \begin{cases} 1 & \text{if } p \equiv 1 \pmod 4 \\ i & \text{if } p \equiv 3 \pmod 4 \end{cases}.$$

This determinant has been used to prove the QUADRATIC RECIPROCITY LAW (Landau 1958, Vardi 1991). The ABSOLUTE VALUES of the PERMANENTS of the Schur matrix of order $2p+1$ are given by 1, 3, 5, 105, 81, 6765, ... (Sloane's A003112, Vardi 1991).

Denote the Schur matrix S_p with the first row and first column omitted by S'_p. Then

$$\operatorname{perm} \mathsf{S}_p = p \operatorname{perm} \mathsf{S}'_p,$$

where perm denoted the PERMANENT (Vardi 1991).

Schur Multiplier

A property of FINITE SIMPLE GROUPS which is known for all such GROUPS.

See also FINITE GROUP, SIMPLE GROUP

Schur Number

The Schur number $S(k)$ is the largest integer n for which the interval $[1, n]$ can be partitioned into k SUM-FREE SETS (Fredricksen and Sweet 2000). $S(k)$ is guaranteed to exist for each k by SCHUR'S PROBLEM. Note the definition of the Schur number as the smallest number $S'(k) = S(k) + 1$ for which such a partition *does not exist* is also prevalent in the literature (Sloane's A030126; Fredricksen and Sweet 2000).

Schur (1916) gave the lower bound

$$S(k) \geq \tfrac{1}{2}(3^n - 1) \tag{1}$$

which is sharp for $n = 1$, 2, and 3 (Guy 1994). The Schur numbers also satisfy the inequality

$$S(k) \geq c(321)^{k/5} > c(1.17176)^k \tag{2}$$

for $k > 5$ and some constant c (Abbott and Moser 1966, Abbott and Hanson 1972, Exoo 1994). SCHUR'S THEOREM also shows that

$$S(n) \leq R(n) - 2. \tag{3}$$

where $R(n)$ is a RAMSEY NUMBER. The first few Schur numbers are 1, 4, 13, 44, $160 \leq S(5) \leq 315$, $S(6) \geq 536$, $S(7) \geq 1680$, ... (Sloane's A045652; Fredricksen and Sweet 2000). $S(4)$ is due to Baumert (Baumert 1965, Abbott and Hanson 1972), the lower bound on $S(5)$ is due to Exoo (1994), and the lower limits on $S(6)$ and $S(7)$ are due to Fredricksen and Sweet (2000).

Schur Transform

For

$$p(z) = a_n z^n + a_{n-1} z^{n-1} + \ldots + a_0, \tag{1}$$

polynomial of degree $n \geq 1$, the Schur transform is defined by the $(n-1)$-degree polynomial

$$Tp(z) \equiv \bar{a}_0 p(z) - a_n p^*(z) \tag{2}$$

$$= \sum_{k=0}^{n-1} (\bar{a}_0 a_k - a_n \bar{a}_{n-k}) z^k \tag{3}$$

where p^* is the RECIPROCAL POLYNOMIAL.

Schur's Partition Theorem

Schur's partition theorem lets $A(n)$ denote the number of partitions of n into parts congruent to ± 1 (mod 6), $B(n)$ denote the number of partitions of n into distinct parts congruent to ± 1 (mod 3), and $C(n)$ the number of partitions of n into parts that differ by at least 3, with the added constraint that the difference between multiples of three is at least 6. Then $A(n) = B(n) = C(n)$ (Schur 1926; Bressoud 1980; Andrews 1986, p. 53).

The values of $A(n) = B(n) = C(n)$ for $n = 1$, 2, ... are 1, 1, 1, 1, 2, 2, 3, 3, 3, 4, 5, 6, 7, 8, 9, 10, 12, 14, 16, 18, ... (Sloane's A003105). For example, for $n = 15$, there are nine partitions satisfying these conditions, as summarized in the following table (Andrews 1986, p. 54).

$A(15) = 9$	$B(15) = 9$	$C(15) = 9$
$13+1+1$	$14+1$	15
$11+1+1+1+1$	$13+2$	$14+1$
$7+7+1$	$11+4$	$13+2$
$7+5+1+1+1$	$10+5$	$12+3$
$7+1+1+1+\ldots+1$	$10+4+1$	$11+4$
$5+5+5$	$8+7$	$10+5$
$5+5+1+1+\ldots+1$	$8+5+2$	$10+4+1$
$5+1+1+\ldots+1$	$8+4+2+1$	$9+5+1$
$1+1+\ldots+1$	$7+5+2+1$	$8+5+2$

The identity $A(n) = B(n)$ can be established using the identity

$$\sum_{n=0}^{\infty} B(n)q^n = (-q;\ q^3)_\infty(-q^2;\ q^3)_\infty \tag{1}$$

$$= \frac{(q^2;\ q^6)_\infty(q^4;\ q^6)_\infty}{(q;\ q^3)_\infty(q^2;\ q^3)_\infty} \tag{2}$$

$$= \frac{(q^2;\ q^6)_\infty(q^4;\ q^6)_\infty}{(q;\ q^6)_\infty(q^4;\ q^6)_\infty(q^2;\ q^6)_\infty(q^5;\ q^6)_\infty} \tag{3}$$

$$= \frac{1}{(q;\ q^6)_\infty(q^5;\ q^6)_\infty} \tag{4}$$

$$= \sum_{n=0}^{\infty} A(n)q^n \tag{5}$$

(Andrews 1986, p. 54). The identity $B(n) = C(n)$ is significantly trickier.

Schur's Problem

Schur (1916) proved that no matter how the set of POSITIVE INTEGERS less than or equal to $\lfloor n!e \rfloor$ (where $\lfloor x \rfloor$ is the FLOOR FUNCTION) is partitioned into n classes, one class must contain INTEGERS x, y, z such that $x + y = z$, where x and y are not necessarily distinct. The least INTEGER $S(n)$ with this property is known as the SCHUR NUMBER. The upper bound has since been slightly improved to $\lfloor n!(e - 1/24) \rfloor$.

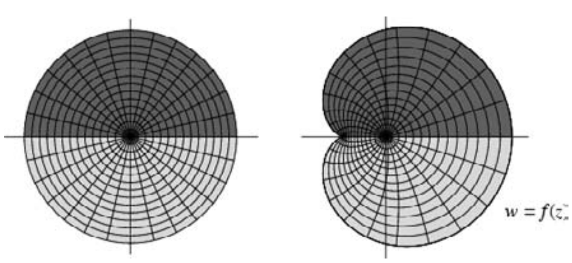
Schur's Theorem



SCHUR'S PARTITION THEOREM, SCHUR'S RAMSEY THEOREM

Schwarz Reflection Principle

Suppose that f is a ANALYTIC FUNCTION which is defined in the UPPER HALF-DISK $\{|z|^2 < 1, \Im[z] > 0\}$. Assume that f extends to a continuous function on the REAL AXIS, and takes on real values on the REAL AXIS. Then f can be extended to an ANALYTIC FUNCTION on the whole disk by the formula

$$f(\bar{z}) = \overline{f(z)},$$

and the values for z reflected across the REAL AXIS are the reflections of $f(z)$ across the REAL AXIS. It is easy to check that the above function is COMPLEX DIFFERENTIABLE in the interior of the LOWER HALF-DISK. What is remarkable is that the resulting function must be analytic along the REAL AXIS as well, despite no assumptions of differentiability.

This is called the Schwarz reflection principle, and is sometimes also known as the Schwarz's symmetric principle (Needham 2000, p. 257). The diagram above shows the reflection principle applied to a function f defined for UPPER HALF-DISK (left figure; red) and its image (right figure; red). The function is real on the real axis, so it is possible to extend the function to the reflected domain (left and right figures; pink).

For the reflected function to be continuous, it is necessary for the values at the boundary to be continuous and to fall on the line being reflected. The reflection principle also applies in the generality of reflecting along any line, not just the REAL AXIS, in which case the function f has to take values along a line in the range. In fact, any arc which has a neighborhood biholomorphic to a straight line can be reflected across. The basic example is the boundary of the UNIT CIRCLE which is mapped to the REAL AXIS by $z \to (iz + 1)/(z + i)$.

The reflection principle can also be used to reflect a HARMONIC FUNCTION which extends continuously to the zero function on its boundary. In this case, for negative y, defining

$$v(x, y) = -v(x, -y)$$

extends v to a harmonic function on the reflected domain. Again note that it is necessary for $v(x, 0) = 0$. This result provides a way of extending a HARMONIC FUNCTION from a given OPEN SET to a larger OPEN SET (Krantz 1999, p. 95).

Schwarz Triangle

The Schwarz triangles are SPHERICAL TRIANGLES which, by repeated reflection in their indices, lead to a set of congruent SPHERICAL TRIANGLES covering the SPHERE a finite number of times.

Schwarz triangles are specified by triples of numbers (p, q, r). There are four "families" of Schwarz triangles, and the largest triangles from each of these families are

$$(2\ 2\ n'),\ \begin{pmatrix}\frac{3}{2} & \frac{3}{2} & \frac{3}{2}\end{pmatrix},\ \begin{pmatrix}\frac{3}{2} & \frac{4}{3} & \frac{4}{3}\end{pmatrix},\ \begin{pmatrix}\frac{5}{4} & \frac{5}{4} & \frac{5}{4}\end{pmatrix}.$$

The others can be derived from

$$(p\ q\ r) = (p\ x\ r_1) + (x\ q\ r_2),$$

where

$$\frac{1}{r_1} + \frac{1}{r_2} = \frac{1}{r}$$

and

$$\cos\left(\frac{\pi}{x}\right) = -\cos\left(\frac{\pi}{x'}\right)$$

$$= \frac{\cos\left(\frac{\pi}{q}\right)\sin\left(\frac{\pi}{r_1}\right) - \cos\left(\frac{\pi}{p}\right)\sin\left(\frac{\pi}{r_2}\right)}{\sin\left(\frac{\pi}{r}\right)}$$

Schwarz-Pick Lemma

Let f be analytic on the UNIT DISK, and assume that

1. $|f(z)| \leq 1$ for all z, and
2. $f(a) = b$ for some $a,\ b \in D(0,\ 1)$, the UNIT DISK.

Then

$$|f'(a)| \leq \frac{1-|b|^2}{1-|a|^2}. \qquad (1)$$

Furthermore, if $f(a_1) = b_1$ and $f(a_2) = b_2$, then

$$\left|\frac{b_2 - b_1}{1 - b_1{}^* b_2}\right| \leq \left|\frac{a_2 - a_1}{1 - \bar{a}_1 a_2}\right|, \qquad (2)$$

where $\bar{z}$ is the COMPLEX CONJUGATE (Krantz 1999, p. 78). As a consequence, if either

$$|f'(a)| \leq \frac{1-|b|^2}{1-|a|^2} \qquad (3)$$

or

$$\left|\frac{b_2 - b_1}{1 - \bar{b}_1 b_2}\right| = \left|\frac{a_2 - a_1}{1 - \bar{a}_1 a_2}\right| \qquad (4)$$

for $a_1\ a_2$, then f is a conformal SELF-MAP of $D(0,\ 1)$ to itself.

Stated succinctly, the Schwarz-Pick lemma guarantees that if f is an analytic map of the DISK $\mathbb{D}$ into $\mathbb{D}$ and f preserves the hyperbolic distance between any two points, then f is a disk map and preserves all distances.

Schwarz's Inequality

Let $\psi_1(x)$ and $\psi_2(x)$ by any two REAL integrable functions in $[a, b]$, then Schwarz's inequality, also called the Cauchy-Schwarz inequality (Gradshteyn and Ryzhik 2000, p. 1099) or Buniakowsky inequality (Hardy *et al.* 1952, p. 16), is given by

$$|\langle\psi_1|\psi_2\rangle|^2 \leq \langle\psi_1|\psi_1\rangle\langle\psi_2|\psi_2\rangle. \quad (1)$$

Written out explicitly

$$\left[\int_a^b \psi_1(x)\psi_2(x)\,dx\right]^2 \leq \int_a^b [\psi_1(x)]^2\,dx \int_a^b [\psi_2(x)]^2\,dx, \quad (2)$$

with equality IFF $g(x) = \alpha f(x)$ with α a constant.

To derive the inequality, let $\psi(x)$ be a COMPLEX FUNCTION and λ a COMPLEX constant such that $\psi(x) \equiv f(x) + \lambda g(x)$ for some f and g. Since $\int \bar{\psi}\psi\,dx \geq 0$, where $\bar{z}$ is the COMPLEX CONJUGATE,

$$\int \bar{\psi}\psi\,dx = \int \bar{f}f\,dx + \lambda \int \bar{f}g\,dx + \bar{\lambda}\int \bar{g}f\,dx + \lambda\bar{\lambda}\int \bar{g}g\,dx \geq 0, \quad (3)$$

with equality when $\psi(x) = 0$. Writing this in compact notation,

$$\langle \bar{f}, f\rangle + \lambda\langle \bar{f}, g\rangle + \bar{\lambda}\langle \bar{g}, f\rangle + \lambda\bar{\lambda}\langle \bar{g}, g\rangle \geq 0. \quad (4)$$

Now define

$$\lambda = -\frac{\langle \bar{g}, f\rangle}{\langle \bar{g}, g\rangle} \quad (5)$$

$$\bar{\lambda} = -\frac{\langle g, \bar{f}\rangle}{\langle \bar{g}, g\rangle}\,dx. \quad (6)$$

Multiply (4) by $\langle \bar{g}, g\rangle$ and then plus in (5) and (6) to obtain

$$\langle \bar{f}, f\rangle\langle \bar{g}, g\rangle - \langle \bar{f}, g\rangle\langle \bar{g}, f\rangle - \langle \bar{g}, \bar{f}\rangle\langle g, \bar{f}\rangle + \langle \bar{g}, f\rangle\langle g, \bar{f}\rangle, \quad (7)$$

which simplifies to

$$\langle \bar{g}, f\rangle\langle \bar{f}, g\rangle \leq \langle \bar{f}, f\rangle\langle \bar{g}, g\rangle \quad (8)$$

so

$$|\langle f, g\rangle|^2 \leq \langle f, f\rangle\langle g, g\rangle. \quad (9)$$

BESSEL'S INEQUALITY follows from SCHWARZ'S INEQUALITY.

Schwarz's Lemma

Let f be analytic on the UNIT DISK, and assume that

1. $|f(z)| \leq 1$ for all z and
2. $f(0) = 0$.

Then $|f(z)| \leq |z|$ and $|f'(0)| \leq 1$.

If either $|f(z)| = |z|$ for some $z \neq 0$ or if $|f'(0)| = 1$, then f is a ROTATION, i.e., $f(z) = az$ for some complex constant a with $|a| = 1$.

Scientific Notation

Scientific notation is the expression of a number n in the form $a \times 10^p$, where

$$p \equiv \lfloor \log_{10} |n| \rfloor$$

is the FLOOR of the base-10 LOGARITHM of n (the "order of magnitude"), and

$$a \equiv \frac{n}{10^p}$$

is a REAL NUMBER satisfying $1 \le |a| < 10$. For example, in scientific notation, the number $n = 101,325$ has order of magnitude

$$p = \lfloor \log_{10} 101,325 \rfloor = \lfloor 5.00572 \rfloor = 5,$$

so n would be written 1.01325×10^5. The special case of 0 does not have a unique representation in scientific notation, i.e., $0 = 0 \times 10^0 = 0 \times 10^1 = \ldots$.

See also CHARACTERISTIC (REAL NUMBER), FIGURES, MANTISSA, SIGNIFICANT DIGITS

s-Cluster

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let an $n \times n$ BINARY MATRIX have entries which are 1 (with probability p) or 0 (with probability $q = 1 - p$). An s-cluster is an isolated group of s adjacent (i.e., horizontally or vertically connected) 1s. Let C_n be the total number of these "SITE" clusters. Then the value

$$K_S(p) = \lim_{n \to \infty} \frac{\langle C_n \rangle}{n^2}, \tag{1}$$

called the MEAN CLUSTER COUNT PER SITE or MEAN CLUSTER DENSITY, exists. Numerically, it is found that $K_S(1/2) \approx 0.065770\ldots$ (Ziff *et al.* 1997).

Considering instead "BOND" clusters (where numbers are assigned to the edges of a grid) and letting C_n be the total number of bond clusters, then

$$K_B(p) \equiv \lim_{n \to \infty} \frac{\langle C_n \rangle}{n^2}, \tag{2}$$

exists. The analytic value is known for $p = 1/2$,

$$K_B(\tfrac{1}{2}) = \tfrac{3}{2}\sqrt{3} - \tfrac{41}{16} \quad (3)$$

(Ziff *et al.* 1997).

Scrawny Cantor Set

A Cantor set C in $\mathbb{R}^3$ is said to be scrawny if for each neighborhood U of an arbitrary point p in C, there is a neighborhood V of p such that every map $f : \mathbb{S}^1 \to V \subset C$ extends to a map $F : \mathbb{B}^2 \to U$ such that $F^{-1}(C)$ is finite. Babich (1992) presents examples of wild Cantor sets of this type and provides a proof that such objects cannot be defined by solid tori.

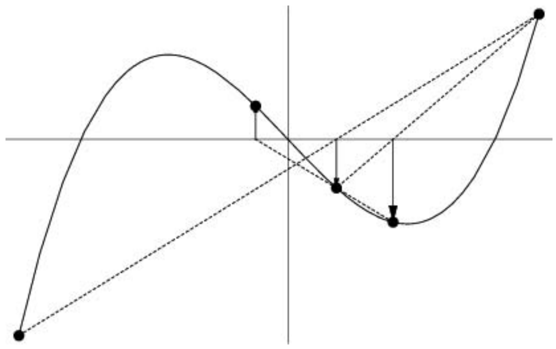
Secant Line



A line joining two points of a curve. As the two points are brought together (or, more precisely, as one is brought towards the other), the secant line tends to a TANGENT LINE. In abstract mathematics, the points

which a secant line connects can be either REAL or COMPLEX CONJUGATE IMAGINARY.

See also BITANGENT, TANGENT LINE, TRANSVERSAL LINE

Secant Method

A ROOT-finding algorithm which assumes a function to be approximately linear in the region of interest. Each improvement is taken as the point where the approximating line crosses the axis. The secant method retains only the most recent estimate, so the root does not necessarily remain bracketed. When the ALGORITHM does converge, its order of convergence is

$$\lim_{k\to\infty} |\epsilon_{k+1}| \approx C|\epsilon|^{\phi}. \tag{1}$$

where C is a constant and ϕ is the GOLDEN MEAN.

$$f'(x_{n-1}) \approx \frac{f(x_{n-1}) - f(x_{n-2})}{x_{n-1} - x_{n-2}} \tag{2}$$

$$f(x_n) \approx f(x_{n-1}) + f'(x_n)(x_n - x_{n-1}) = 0 \tag{3}$$

$$f(x_{n-1}) + \frac{f(x_{n-1}) - f(x_{n-2})}{x_{n-1} - x_{n-2}}(x_n - x_{n-1}) = 0. \tag{4}$$

so

$$x_n = x_{n-1} - \frac{f(x_{n-1})(x_{n-1} - x_{n-2})}{f(x_{n-1}) - f(x_{n-2})}. \tag{5}$$

Secant Number

A number, more commonly called an EULER NUMBER, giving the number of EVEN ALTERNATING PERMUTATIONS. The term ZIG NUMBER is sometimes also used. The first few are 1, 5, 61, 1385, ... (Sloane's A000364).

Second Curvature

TORSION (DIFFERENTIAL GEOMETRY)

Second Derivative Test

Suppose $f(x)$ is a FUNCTION of x which is twice DIFFERENTIABLE at a STATIONARY POINT x_0.

1. If $f''(x_0) > 0$, then f has a RELATIVE MINIMUM at x_0.
2. If $f''(x_0) < 0$, then f has a RELATIVE MAXIMUM at x_0.

The EXTREMUM TEST gives slightly more general conditions under which a function with $f''(x_0) = 0$ is a maximum or minimum.

If $f(x, y)$ is a 2-D FUNCTION which has a RELATIVE EXTREMUM at a point (x_0, y_0) and has CONTINUOUS PARTIAL DERIVATIVES at this point, then $f_x(x_0, y_0) = 0$ and $f_y(x_0, y_0) = 0$. The second PARTIAL DERIVATIVES test classifies the point as a MAXIMUM or MINIMUM. Define the DISCRIMINANT as

$$D \equiv f_{xx}f_{yy} - f_{xy}f_{yx} = f_{xx}f_{yy} - f_{xy}^2.$$

1. If $D > 0$, $f_{xx}(x_0, y_0) > 0$ and $f_{xx}(x_0, y_0) + f_{yy}(x_0, y_0) > 0$, the point is a RELATIVE MINIMUM.
2. If $D > 0$, $f_{xx}(x_0, y_0) < 0$, and $f_{xx}(x_0, y_0) + f_{yy}(x_0, y_0) < 0$, the point is a RELATIVE MAXIMUM.
3. If $D < 0$, the point is a SADDLE POINT.
4. If $D = 0$, higher order tests must be used.

Second Fundamental Form

Let M be a regular surface with $\mathbf{v_p}$, $\mathbf{w_p}$ points in the tangent space $M_\mathbf{p}$ of M. For $M \in \mathbb{R}^3$, the second fundamental form is the symmetric bilinear form on the tangent space $M_\mathbf{p}$,

$$\mathbf{II}(\mathbf{v_p},\ \mathbf{w_p}) = S(\mathbf{v_p}) \cdot \mathbf{w_p}. \tag{1}$$

where S is the shape operator. The second fundamental form satisfies

$$\mathbf{II}(a\mathbf{x}_u + b\mathbf{x}_v,\ a\mathbf{x}_u + b\mathbf{x}_v) = ea^2 + 2fab + gb^2 \tag{2}$$

for any nonzero tangent vector.

The second fundamental form is given explicitly by

$$e\,du^2 + 2f\,du\,dv + g\,dv^2 \tag{3}$$

where

$$e = \sum_i X_i \frac{\partial^2 x_i}{\partial u^2} \tag{4}$$

$$f = \sum_i X_i \frac{\partial^2 x_i}{\partial u\,\partial v} \tag{5}$$

$$g = \sum_i X_i \frac{\partial^2 x_i}{\partial v^2} \tag{6}$$

and X_i are the direction cosines of the surface normal. The second fundamental form can also be written

$$e = -\mathbf{N}_u \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{uv} \tag{7}$$

$$f = -\mathbf{N}_v \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uv} = \mathbf{N}_{vu} \cdot \mathbf{x}_{vu}$$

$$= -\mathbf{N}_u \cdot \mathbf{x}_v \tag{8}$$

$$g = -\mathbf{N}_v \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{vv}, \tag{9}$$

where $\mathbf{N}$ is the normal vector, $\mathbf{x} : U \to \mathbb{R}^3$ is a regular patch, and $\mathbf{x}_u$ and $\mathbf{x}_v$ are the partial derivatives of $\mathbf{x}$ with respect to parameters u and v, respectively, or

$$e = \frac{\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)}{\sqrt{EG - F^2}} \tag{10}$$

$$f = \frac{\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)}{\sqrt{EG - F^2}} \tag{11}$$

$$g = \frac{\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)}{\sqrt{FG - F^2}}. \tag{12}$$

Second Fundamental Tensor

Weingarten Map

Second Kind

Special functions which arise as solutions to second order ordinary differential equations are commonly said to be "of the first kind" if they are *nonsingular* at the origin, while the linearly independent solutions which are *singular* are said to be "of the second kind." Common examples of functions of the second kind defined in this way include the Bessel function of the second kind, Chebyshev polynomial of the second kind, confluent hypergeometric function of the second kind, Hankel function of the second kind, and so on.

The term "second kind" is also used in a more general context to distinguish between two or more types of mathematical objects which, however, all satisfy some common overall property. Examples of objects of this kind include the Christoffel symbol of the second kind, elliptic integral of the second kind, Fredholm integral equation of the second kind, Stirling number of the second kind, Volterra integral equation of the second kind, and so on.

See also Bessel Function of the Second Kind, Chebyshev Polynomial of the Second Kind, Confluent Hypergeometric Function of the Second Kind, Elliptic Integral of the Second Kind, First Kind, Fredholm Integral Equation of the Second Kind, Hankel Function of the Second Kind, Special Function, Stirling Number of the Second Kind, Third Kind, Volterra Integral Equation of the Second Kind

Section

A section of a solid is the plane figure cut from the solid by passing a plane through it (Kern and Bland 1948, p. 18).

TION (TANGENT BUNDLE), SPIRIC SECTION, SURFACE OF SECTION, TORIC SECTION

References
Kern, W. F. and Bland, J. R. *Solid Mensuration with Proofs, 2nd ed.* New York: Wiley, 1948.

Section (Bundle)

A section of a FIBER BUNDLE gives an element of the fiber over every point in B. Usually it is described as a map $s : B \to E$ such that $\pi \circ s$ is the identity on B. A real-valued function on a manifold M is a section of the trivial LINE BUNDLE $M \times \mathbb{R}$. Another common example is a VECTOR FIELD, which is a section of the TANGENT BUNDLE.

See also FIBER BUNDLE, TANGENT BUNDLE, VECTOR BUNDLE, ZERO SECTION

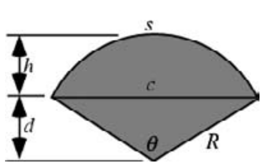
Section (Pencil)

The lines of a PENCIL joining the points of a RANGE to another POINT.

See also PENCIL, RANGE (LINE SEGMENT)

Section (Tangent Bundle)

A VECTOR FIELD is a section of its TANGENT BUNDLE, meaning that to every point x in a MANIFOLD M, a VECTOR $X(x) \in T_x M$ is associated, where T_x is the TANGENT SPACE.



See also TANGENT BUNDLE, TANGENT SPACE

Sectional Curvature

The mathematical object κ which controls the rate of geodesic deviation.

See also BISHOP'S INEQUALITY, CHEEGER'S FINITENESS THEOREM, GEODESIC

Sector

A WEDGE obtained by taking a portion of a DISK with CENTRAL ANGLE $\theta < \pi$ radians (180°), illustrated above as the shaded region. A sector of π radians would be a SEMICIRCLE. Let R be the radius of the CIRCLE, c the CHORD length, s the ARC LENGTH, h the height of the arced portion, and d the height of the triangular portion. Then

$$R = h + d \quad (1)$$

$$s = R\theta \quad (2)$$

$$d = R\cos\left(\tfrac{1}{2}\theta\right) \quad (3)$$

$$= \tfrac{1}{2}c\cot\left(\tfrac{1}{2}\theta\right) \quad (4)$$

$$= \tfrac{1}{2}\sqrt{4R^2 - c^2} \quad (5)$$

$$c = 2R\sin\left(\tfrac{1}{2}\theta\right) \quad (6)$$

$$= 2d\tan\left(\tfrac{1}{2}\theta\right) \quad (7)$$

$$= 2\sqrt{R^2 - d^2} \quad (8)$$

$$= 2\sqrt{h(2R - h)}. \quad (9)$$

The ANGLE θ obeys the relationships

$$\theta = \frac{s}{R} = 2\cos^{-1}\left(\frac{d}{R}\right) = 2\tan^{-1}\left(\frac{c}{2d}\right) = 2\sin^{-1}\left(\frac{c}{2R}\right). \quad (10)$$

The AREA of the sector is

$$A = \tfrac{1}{2}Rs = \tfrac{1}{2}R^2\theta \quad (11)$$

(Beyer 1987).

Seek Time

POINT-POINT DISTANCE–1-D

Segment

A portion of a DISK whose upper boundary is a circular ARC and whose lower boundary is a CHORD making a CENTRAL ANGLE $\theta < \pi$ radians (180°), illustrated above as the shaded region. Let R be the radius of the CIRCLE, c the CHORD length, s the ARC LENGTH, h the height of the arced portion, and d the height of the triangular portion. Then

$$R = h + d \tag{1}$$

$$s = R\theta \tag{2}$$

$$d = R\cos\left(\tfrac{1}{2}\theta\right) \tag{3}$$

$$= \tfrac{1}{2}c\cot\left(\tfrac{1}{2}\theta\right) \tag{4}$$

$$= \tfrac{1}{2}\sqrt{4R^2 - c^2} \tag{5}$$

$$c = 2R\sin\left(\tfrac{1}{2}\theta\right) \tag{6}$$

$$= 2d\tan\left(\tfrac{1}{2}\theta\right) \tag{7}$$

$$= 2\sqrt{R^2 - d^2} \tag{8}$$

$$= 2\sqrt{h(2R - h)}. \tag{9}$$

The ANGLE θ obeys the relationships

$$\theta = \frac{s}{R} = 2\cos^{-1}\left(\frac{d}{R}\right) = 2\tan^{-1}\left(\frac{c}{2d}\right)$$

$$= 2\sin^{-1}\left(\frac{c}{2R}\right). \tag{10}$$

The AREA of the segment is then

$$A = A_{\text{sector}} - A_{\text{isosocles triangle}} \tag{11}$$

$$= \tfrac{1}{2}R^2(\theta - \sin\theta) \tag{12}$$

$$= \tfrac{1}{2}(Rs - cd) \tag{13}$$

$$= R^2\cos^{-1}\left(\frac{d}{R}\right) - d\sqrt{R^2 - d^2} \tag{14}$$

$$= R^2\cos^{-1}\left(\frac{R-h}{R}\right) - (R-h)\sqrt{2Rh - h^2}. \tag{15}$$

where the formula for the ISOSCELES TRIANGLE in terms of the VERTEX angle has been used (Beyer 1987). Approximate formulas for the ARC LENGTH and AREA are

$$s \approx \sqrt{c^2 + \tfrac{16}{3}h^2} \tag{16}$$

accurate to within 0.3% for $0° \leq \theta \leq 90°$, and

$$A \approx \tfrac{2}{3}ch + \frac{h_3}{2c}. \tag{17}$$

accurate to within 0.1% for $0° \leq \theta \leq 150°$ and 0.8% for $150° \leq \theta \leq 180°$ (Harris and Stocker 1998).

Seifert Form

For K a given KNOT in $\mathbb{S}^3$, choose a SEIFERT SURFACE M^2 in $\mathbb{S}^3$ for K and a bicollar $\hat{M}\times[-1, 1]$ in $\mathbb{S}^3 - K$. If $x \in H_1(M)$ is represented by a 1-cycle in $\hat{M}$, let x^+ denote the homology cycle carried by $x\times 1$ in the bicollar. Similarly, let x^- denote $x\times -1$. The function $f: H_1(\hat{M})\times H_1(\hat{M})\to Z$ defined by

$$f(x, y) = \mathrm{lk}(x, y^+),$$

where lk denotes the LINKING NUMBER, is called a Seifert form for K.

See also SEIFERT MATRIX

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, pp. 200–201, 1976.

Seifert Matrix

Given a SEIFERT FORM $f(x, y)$, choose a basis $e_1, ..., e_{2g}$ for $H_1(\hat{M})$ as a $\mathbb{Z}$-module so every element is uniquely expressible as

$$n_1 e_1 + \ldots + n_{2g} e_{2g} \tag{1}$$

with n_i integer. Then define the Seifert matrix V as the $2g\times 2g$ INTEGER MATRIX with entries

$$v_{ij} = \mathrm{lk}\left(e_i,\ e_j^+\right). \tag{2}$$

For example, the right-hand TREFOIL KNOT has Seifert matrix

$$V = \begin{bmatrix} -1 & 1 \\ 0 & -1 \end{bmatrix}. \tag{3}$$

A Seifert matrix is not a KNOT INVARIANT, but it can be used to distinguish between different SEIFERT SURFACES for a given knot.

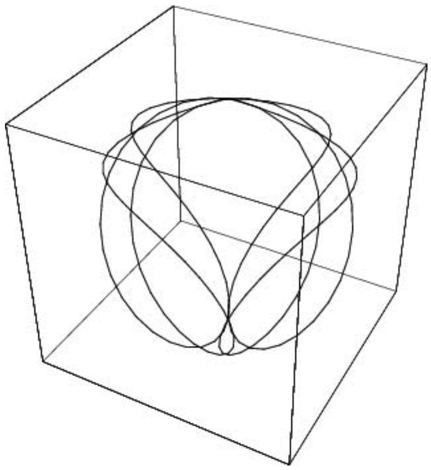
See also ALEXANDER MATRIX

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, pp. 200–203, 1976.

Seifert Surface

An orientable surface with one boundary component such that the boundary component of the surface is a given KNOT K. In 1934, Seifert proved that such a surface can be constructed for any KNOT. The process of generating this surface is known as Seifert's algorithm. Applying Seifert's algorithm to an alternating projection of an alternating knot yields a Seifert surface of minimal GENUS.



There are KNOTS for which the minimal genus Seifert surface cannot be obtained by applying Seifert's algorithm to any projection of that KNOT, as proved by Morton in 1986 (Adams 1994, p. 105).

Selberg's Formula

Let x be a positive number, and define

$$\lambda(d) = \mu(d)\left[\ln\left(\frac{x}{d}\right)\right]^2 \tag{1}$$

$$f(n) = \sum_{d}\lambda(d). \tag{2}$$

where the sum extends over the divisors d of n, and $\mu(n)$ is the MÖBIUS FUNCTION. Then

$$S = \sum_{n \leq x} f(n) = 2x \ln x + o(x \ln x) \quad (3)$$

(Nagell 1951, p. 286).

Self Number

A number (usually base 10 unless specified otherwise) which has no GENERATOR. Such numbers were originally called COLUMBIAN NUMBERS (S. 1974). There are infinitely many such numbers, since an infinite sequence of self numbers can be generated from the RECURRENCE RELATION

$$C_k = 8 \cdot 10^{k-1} + C_{k-1} + 8, \quad (1)$$

for $k = 2, 3, \ldots$, where $C_1 = 9$. The first few self numbers are 1, 3, 5, 7, 9, 20, 31, 42, 53, 64, 75, 86, 97, ... (Sloane's A003052).

An infinite number of 2-self numbers (i.e., base-2 self numbers) can be generated by the sequence

$$C_k = 2^j + C_{k-1} + 1 \quad (2)$$

for $k = 1, 2, \ldots$, where $C_1 = 1$ and j is the number of digits in C_{k-1}. An infinite number of n-self numbers can be generated from the sequence

$$C_k = (n-2)n^{k-1} + C_{k-1} + (n-2) \quad (3)$$

for $k = 2, 3, \ldots$, and

$$C_1 = \begin{cases} n-1 & \text{for } n \text{ even} \\ n-2 & \text{for } n \text{ odd}. \end{cases} \quad (4)$$

Joshi (1973) proved that if k is ODD, then m is a k-self number IFF m is ODD. Patel (1991) proved that $2k$, $4k+2$, and k^2+2k+1 are k-self numbers in every EVEN base $k > 4$.

Self-Adjoint

Consider a second-order differential operator

$$\tilde{\mathcal{L}}u(x) \equiv p_0 \frac{d^2u}{dx^2} + p_1 \frac{du}{dx} + p_2 u, \quad (1)$$

where $u \equiv u(x)$ and $p_i \equiv p_i(x)$ are REAL FUNCTIONS of x on the region of interest $[a, b]$ with $2-i$ continuous derivatives and with $p_0(x) \neq 0$ on $[a, b]$. This means that there are no singular points in $[a, b]$. Then the ADJOINT operator $\tilde{\mathcal{L}}^*$ is defined by

$$\tilde{\mathcal{L}}^* u \equiv \frac{d^2}{dx^2}(p_0 u) - \frac{d}{dx}(p_1 u) + p_2 u \quad (2)$$

$$= p_0 \frac{d^2u}{dx^2} + (2p_0' - p_1)\frac{du}{dx} + (p_0'' - p_1' + p_2)u. \quad (3)$$

In order for the operator to be self-adjoint, i.e.,

$$\tilde{\mathcal{L}} = \tilde{\mathcal{L}}^*. \quad (4)$$

the second terms in (1) and (3) must be equal, so

$$p_0'(x) = p_1(x). \quad (5)$$

This also guarantees that the third terms are equal, since

$$p_0'(x) = p_1(x) \Rightarrow p_0''(x) = p_1'(x). \quad (6)$$

so (3) becomes

$$\tilde{\mathcal{L}}u = \tilde{\mathcal{L}}^* u = p_0 \frac{d^2u}{dx^2} + p_0' \frac{du}{dx} + p_2 u \quad (7)$$

$$= \frac{d}{dx}\left(p_0 \frac{du}{dx}\right) + p_2 u = 0. \quad (8)$$

The differential operators corresponding to the LE-

GENDRE DIFFERENTIAL EQUATION and the equation of SIMPLE HARMONIC MOTION are self-adjoint, while those corresponding to the LAGUERRE DIFFERENTIAL EQUATION and HERMITE DIFFERENTIAL EQUATION are not.

A nonself-adjoint second-order linear differential operator can always be transformed into a self-adjoint one using STURM-LIOUVILLE THEORY. In the special case $p_2(x)=0$, (8) gives

$$\frac{d}{dx}\left[p_0(x)\frac{du}{dx}\right]=0 \quad (9)$$

$$p_0(x)\frac{du}{dx}=C \quad (10)$$

$$du=C\,\frac{dx}{p_0(x)} \quad (11)$$

$$u=C\int\frac{dx}{p_0(x)}, \quad (12)$$

where C is a constant of integration.

A self-adjoint operator which satisfies the BOUNDARY CONDITIONS

$$\bar{v}pU'|_{x=a}=\bar{v}pU'|_{x=b} \quad (13)$$

is automatically a HERMITIAN OPERATOR.

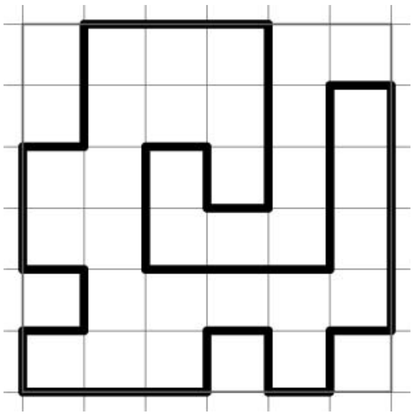
Self-Adjoint Matrix



A MATRIX A for which

$$\mathsf{A}^* \equiv \overline{\mathsf{A}^{\mathrm{T}}} = \mathsf{A}.$$

where the ADJOINT MATRIX is denoted A^*, A^{T} is the MATRIX TRANSPOSE, and $\bar{z}$ is the COMPLEX CONJUGATE. If a MATRIX is self-adjoint, it is said to be HERMITIAN.

See also ADJOINT, HERMITIAN MATRIX, MATRIX TRANSPOSE

Self-Avoiding Polygon

A LATTICE POLYGON consisting of a closed SELF-AVOIDING WALK on a square lattice. The perimeter, horizontal perimeter, vertical perimeter, and AREA are all WELL DEFINED for self-avoiding polygons. Special classes of self-avoiding polygons include the BAR GRAPH POLYGON, CONVEX POLYGON, FERRERS GRAPH POLYGON, STACK POLYGON, and STAIRCASE POLYGON. Self-avoiding polygon are used in physics to model crystal growth and polymers (Bousquet-Mélou 1992).

Enumerating self-avoiding polygons according to perimeter or area is an unsolved problem (Bousquet-Mélou *et al.* 1999).

See also POLYOMINO, SELF-AVOIDING WALK, STAIRCASE POLYGON

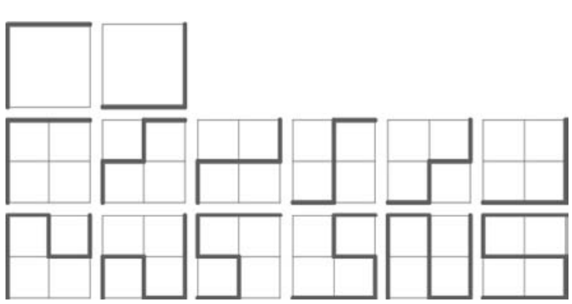
Self-Avoiding Walk

N.B. A detailed online essay by S. Finch was the starting point for this entry.



A self-avoiding walk is a path from one point to another which never intersects itself. Such paths are usually considered to occur on lattices, so that steps are only allowed in a discrete number of directions and of certain lengths.

Consider a self-avoiding walk on a 2-D $n \times n$ square grid (i.e., a lattice path which never visits the same lattice point twice) which starts at the origin, takes first step in the positive horizontal direction, and is restricted to nonnegative grid points only. The number of such paths of $n = 1, 2, \ldots$ steps are 1, 2, 5, 12, 30, 73, 183, 456, 1151, ... (Sloane's A046170).

Similarly, consider a self-avoiding walk which starts at the origin, takes first step in the positive horizontal direction, is *not* restricted to nonnegative grid points only, but which *is* restricted to take an up step before taking the first down step. The number of such paths of $n = 1, 2, \ldots$ steps are 1, 2, 5, 13, 36, 98, 272, 740, 2034, ... (Sloane's A046171).

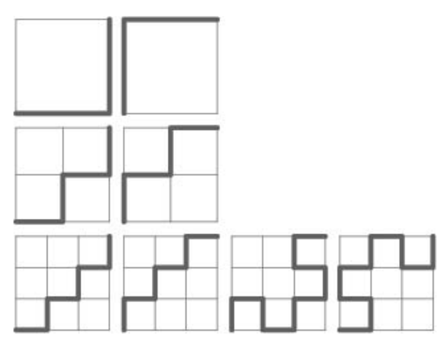
Self-avoiding rook walks are walks on an $m \times n$ grid which start from (0, 0), end at (m, n), and are composed of only horizontal and vertical steps. The following table gives the first few numbers $R(m, n)$ of such walks for small m and n. The values for $m = n = 1, 2, \ldots$ are 2, 12, 184, 8512, 1262816, ... (Sloane's A007764).

m	2	3	4	5	6
2	2				
3	4	12			
4	8	38	184		
5	16	125	976	8512	
6	32	414	5382	79384	1262816

There are a number of known formulas for computing $R(m, n)$ for small m, n. For example,

$$R(m,\ 2) = 2^{m-1}.$$

There is a RECURRENCE RELATION for $R(m, 3)$, given by $R(1, 3) = 1$, $R(2, 3) = 4$, $R(3, 3) = 12$, $R(4, 3) = 38$, and



$$R(m,\ 3) = 4R(m-1,\ 3) - 3R(m-2,\ 3) + 2R(m-3,\ 3) + R(m-3,\ 4)$$

for $m \geq 5$, as well as the GENERATING FUNCTION

$$R(m,\ 3) = \frac{1}{(m-1)!} \frac{d^{m-1}}{dx^{m-1}} \frac{(x-1)(x+1)}{(x^2+3x-1)(x^2-x+1)}\bigg|_{x=0}$$

(Abbott and Hanson 1978, Finch).

A related sequence is the number of shapes which can be formed by bending a piece of wire of length n in the plane, where bends are of 0 or $\pm 90°$ and the wire may cross itself at right angles but not pass over itself. The number of shapes for wires of length 1, 2, ... are 1, 2, 4, 10, 24, 66, 176, 493, ... (Sloane's A001997).

Consider a self-avoiding walk on a 2-D $n \times n$ square grid from one corner to another such that no two consecutive steps are in the same direction. The number of such paths for $n = 1, 2, \ldots$ are 1, 2, 2, 4,

10, 36, 188, ... (Sloane's A034165; counting the number of paths on the 1×1 point "lattice" as 1), and the maximum lengths of these paths are 0, 2, 4, 10, 12, 26, 36, ... (Sloane's A034166).

Self-Avoiding Walk Connective Constant

Let the number of random walks on a d-D hypercubic lattice starting at the origin which never land on the same lattice point twice in n steps be denoted $c_d(n)$. The first few values are

$$c_d(0) = 1 \tag{1}$$

$$c_d(1) = 2d \tag{2}$$

$$c_d(2) = 2d(2d-1). \tag{3}$$

In general,

$$d^n \le c_d(n) \le 2d(2d-1)^{n-1} \tag{4}$$

(Pönitz and Tittman 2000), with tighter bounds given by Madras and Slade (1993). Conway and Guttmann (1996) have enumerated walks of up to length 51.

The so-called "connective constants" are defined by

$$\mu_d \equiv \lim_{n\to\infty} [c_d(n)]^{1/n} \tag{5}$$

and are known to exist and be finite. The best ranges for these constants are

$$\mu_2 \in [2.62002,\ 2.679192495] \tag{6}$$

$$\mu_3 \in [4.572140,\ 4.7476] \tag{7}$$

$$\mu_4 \in [6.742945,\ 6.8179] \tag{8}$$

$$\mu_5 \in [8.828529,\ 8.88602] \tag{9}$$

$$\mu_6 \in [10.874038,\ 10.8886] \tag{10}$$

(Beyer and Wells 1972, Noonan 1998, Finch). The upper bound of μ_2 improves on the 2.6939 found by Noonan 1998 and was computed by Pönitz and Tittman (2000).

For the triangular lattice in the plane, $\mu < 4.278$ (Alm 1993), and for the hexagonal planar lattice, it is conjectured that

$$\mu = \sqrt{2+\sqrt{2}} \tag{11}$$

(Madras and Slade 1993).

The following limits are also believed to exist and to be finite:

$$\begin{cases} \lim_{n\to\infty} \dfrac{c(n)}{\mu^n n^{\gamma-1}} & \text{for } d \ne 4 \\ \lim_{n\to\infty} \dfrac{c(n)}{\mu^n n^{\gamma-1}(\ln n)^{1/4}} & \text{for } d = 4. \end{cases} \tag{12}$$

where the critical exponent $\gamma = 1$ for $d > 4$ (Madras and Slade 1993) and it has been conjectured that

$$\gamma = \begin{cases} \frac{43}{32} & \text{for } d = 2 \\ 1.162\ldots & \text{for } d = 3 \\ 1 & \text{for } d = 4. \end{cases} \tag{13}$$

Define the mean square displacement over all n-step self-avoiding walks ω as

$$s(n) \equiv \langle |\omega(n)|^2 \rangle = \frac{1}{c(n)} \sum_{\omega} |\omega(n)|^2. \tag{14}$$

The following limits are believed to exist and be finite:

$$\begin{cases} \lim_{n\to\infty} \dfrac{s(n)}{n^{2\nu}} & \text{for } d \ne 4 \\ \lim_{n\to\infty} \dfrac{s(n)}{n^{2\nu}(\ln n)^{1/4}} & \text{for } d = 4. \end{cases} \tag{15}$$

where the critical exponent $\nu = 1/2$ for $d > 4$ (Madras and Slade 1993), and it has been conjectured that

$$\nu = \begin{cases} \frac{3}{4} & \text{for } d = 2 \\ 0.59\ldots & \text{for } d = 3 \\ \frac{1}{2} & \text{for } d = 4. \end{cases} \tag{16}$$

Self-Complementary Graph

A self-complementary graph is a GRAPH which is isomorphic to its GRAPH COMPLEMENT. The numbers of simple self-complementary graphs on $n = 1, 2, \ldots$ nodes are 1, 0, 0, 1, 2, 0, 0, 10, ... (Sloane's A000171). The first few of these compose to the trivial graph on one node, the PATH GRAPH P_4, and the CYCLE GRAPH C_5.

All self-complementary graphs have GRAPH DIAMETER 2 or 3 (Sachs 1962; Skiena 1990, p. 187).

See also GRAPH COMPLEMENT, ISOMORPHIC GRAPHS

Self-Conjugate Partition

A PARTITION whose CONJUGATE PARTITION is equivalent to itself. The FERRERS DIAGRAMS corresponding to the self-conjugate partitions for $3 \leq n \leq 10$ are illustrated above. The numbers of self-conjugate partitions of $n = 1, 2, \ldots$ are 1, 0, 1, 1, 1, 1, 1, 2, 2, 2, 2, 3, 3, 3, 4, 5, 5, 5, 6, 7, ... (Sloane's A000700). The number of self-conjugate partitions S_n of n is equal to the number of partitions of n into distinct odd parts, and has generating function

$$\prod_{k=0}^{\infty} 1 + x^{2k+1} = \sum_{k=0}^{\infty} S_k x^k,$$

and $(-1)^n S_n$ has GENERATING FUNCTION

$$\prod_{k=1}^{\infty} \frac{1}{1 + x^k} = \sum_{k=0}^{\infty} (-1)^k S_k x^k.$$

Selfridge's Conjecture

There exist infinitely many $n > 0$ with $p_n^2 > p_{n-i}p_{n+i}$ for all $i < n$, where p_n is the nth PRIME. Also, there exist infinitely many $n > 0$ such that $2p_n < p_{n-i} + p_{n+i}$ for all $i < n$.

Self-Similarity

An object is said to be self-similar if it looks "roughly" the same on any scale. FRACTALS are a particularly interesting class of self-similar objects. Self-similar objects with parameters N and s are described by a power law such as

$$N = s^d,$$

where

$$d = \frac{\ln N}{\ln s}$$

is the "DIMENSION" of the scaling law, known as the HAUSDORFF DIMENSION.

Self-Transversality Theorem

Let j, r, and s be distinct INTEGERS (mod n), and let W be the point of intersection of the side or diagonal V, V_{i+j} of the n-gon $P = [V_1 \ldots V_n]$ with the transversal $V_{i+r}\,V_{i+s}$. Then a NECESSARY and SUFFICIENT condition for

$$\prod_{i=1}^{n}\left[\frac{V_i W_i}{W_i V_{i+j}}\right] = (-1)^n,$$

where $AB \| CD$ and

$$\left[\frac{AB}{CD}\right],$$

is the ratio of the lengths $[A, B]$ and $[C, D]$ with a plus or minus sign depending on whether these segments have the same or opposite direction, is that

1. $n = 2m$ is EVEN with $j \equiv m \pmod{n}$ and $s \equiv r + m \pmod{n}$,
2. n is arbitrary and either $s \equiv 2r$ and $j \equiv 3r$, or
3. $r \equiv 2s \pmod{n}$ and $j \equiv 3s \pmod{n}$.

Sellke's Self-Describing Sequence

KOLAKOSKI SEQUENCE

Selmer Group

A GROUP which is related to the TANIYAMA-SHIMURA CONJECTURE.

See also TANIYAMA-SHIMURA CONJECTURE

Semialgebraic Set

A subset of $\mathbb{R}^n$ which is a finite Boolean combination of sets OF THE FORM $\{\bar{x} = (x_1, \ldots, x_n) : f(\bar{x}) > 0\}$ and $\{\bar{x} : g(\bar{x}) = 0\}$, where $f,\ g \in \mathbb{R}[X_1, \ldots, X_n]$.

By TARSKI'S THEOREM, the solution set of a QUANTIFIED SYSTEM of real algebraic equations and inequalities is a semialgebraic set (Strzebonski 2000).

See also TARSKI'S THEOREM

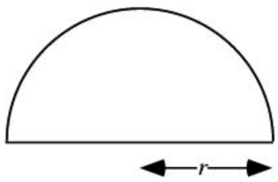
Semianalytic



$X \subseteq \mathbb{R}^n$ is semianalytic if, for all $x \in \mathbb{R}^n$, there is an open neighborhood U of x such that $X \cap U$ is a finite Boolean combination of sets $\{\bar{x} \in U : f(\bar{x}) = 0\}$ and $\{\bar{x} \in U : g(\bar{x}) > 0\}$, where $f,\ g : U \to \mathbb{R}$ are ANALYTIC.

See also ANALYTIC FUNCTION, PSEUDOANALYTIC FUNCTION, SUBANALYTIC

References

Semicircle

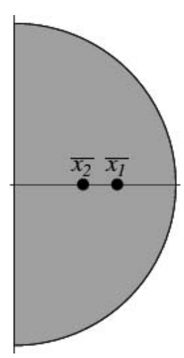
Half a CIRCLE. The AREA of a semicircle of radius r is given by

$$A = \int_0^r \int_{-\sqrt{r^2-x^2}}^{\sqrt{r^2-x^2}} dx\, dy = 2\int_0^r \sqrt{r^2-x^2}\, dx = \tfrac{1}{2}\pi r^2. \quad (1)$$

The weighted mean of y is

$$\langle x\rangle_2 = 2\int_0^r x\sqrt{r^2-x^2}\, dx = \tfrac{2}{3} r^3. \quad (2)$$

The semicircle is the CROSS SECTION of a HEMISPHERE for any PLANE through the z-AXIS.
The perimeter of the curved boundary is given by



$$s = \int_{-r}^r \sqrt{1+x'^2}\, dy. \quad (3)$$

With $x = \sqrt{r^2-y^2}$, this gives

$$s = \pi r. \quad (4)$$

The PERIMETER of the semicircular lamina is then

$$L = 2r + \pi r = r(2+\pi). \quad (5)$$

The weighted value of x of the semicircular curve is given by

$$\langle x\rangle_1 = \int_{-r}^r x\sqrt{1+x'^2}\, dy = \int_{-r}^r r\, dy = 2r^2, \quad (6)$$

so the CENTROID is

$$\bar{x}_1 = \frac{\langle x\rangle_1}{A} = \frac{2r}{\pi}. \quad (7)$$

The CENTROID of the semicircular lamina is given by

$$\bar{x}_2 = \frac{\langle x\rangle_2}{A} = \frac{4r}{3\pi} \quad (8)$$

(Kern and Bland 1948, p. 113).

Semicubical Parabola

A PARABOLA-like curve with Cartesian equation

$$y = ax^{3/2}, \quad (1)$$

PARAMETRIC EQUATIONS

$$x = t^2 \quad (2)$$

$$y = at^3 \quad (3)$$

and POLAR COORDINATES,

$$r = \frac{\tan^2\theta \sec\theta}{a}. \quad (4)$$

The semicubical parabola is the curve along which a particle descending under gravity describes equal vertical spacings within equal times, making it an ISOCHRONOUS CURVE. The problem of finding the

curve having this property was posed by Leibniz in 1687 and solved by Huygens (MacTutor Archive).

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = \tfrac{1}{27}\left(4 + 9t^2\right)^{3/2} - \tfrac{8}{27} \quad (5)$$

$$\kappa(t) = \frac{6}{t(4 + 9t^2)^{3/2}} \quad (6)$$

$$\phi(t) = \tan^{-1}\left(\tfrac{3}{2}t\right). \quad (7)$$

Semiderivative

A FRACTIONAL DERIVATIVE of order 1/2. The semiderivative of t^λ is given by

$$D^{1/2}t^\lambda = \frac{t^{\lambda-1/2}\Gamma(\lambda+1)}{\Gamma\left(\lambda+\frac{1}{2}\right)},$$

so the semiderivative of the CONSTANT FUNCTION $f(t) = c$ is given by

$$D^{1/2}c = c \lim_{\lambda\to 0} \frac{t^{\lambda-1/2}\Gamma(\lambda+1)}{\Gamma\left(\lambda+\frac{1}{2}\right)} = \frac{c}{\sqrt{\pi t}}.$$

Semidirect Product

A "split" extension G of GROUPS N and F which contains a SUBGROUP $\bar{F}$ isomorphic to F with $G = \bar{F}\bar{N}$ and $\bar{F} \cap \bar{N} = \{e\}$ (Ito 1987, p. 710). Then the semidirect product of a GROUP G by a group H, denoted $H \times G$ (or sometimes $H : G$) with homomorphism T is given by

$$(g,\ h)(g',\ h') = (gg', (h(g'T))h'),$$

where $g,\ g' \in G,\ h,\ h' \in H$, and $T \in \mathrm{Hom}(F,\ \mathrm{Aut}(H))$ (Suzuki 1982, p. 67; Scott 1987, p. 213). Note that the semidirect product of two groups is *not* uniquely defined.

The semidirect product of a group G by a group H can also be defined as a group $S = GH$ which is the product of its subgroups G and H, where H is normal in S and $G \cap H = \{1\}$. If G is also normal in S, then the semidirect product becomes a GROUP DIRECT PRODUCT (Shmel'kin 1988, p. 247).

Semiflow

An ACTION with $G = \mathbb{R}^+$.

See also FLOW

Semigroup

A mathematical object defined for a set and a BINARY OPERATOR in which the multiplication operation is ASSOCIATIVE. No other restrictions are placed on a semigroup; thus a semigroup need not have an IDENTITY ELEMENT and its elements need not have inverses within the semigroup. A semigroup is an ASSOCIATIVE GROUPOID.

A semigroup can be empty. The total number of semigroups of order n are 1, 4, 18, 126, 1160, 15973, 836021, ... (Sloane's A001423). The number of semigroups of order n with one IDEMPOTENT are 1, 2, 5, 19, 132, 3107, 623615, ... (Sloane's A002786), and with two IDEMPOTENTS are 2, 7, 37, 216, 1780, 32652, ... (Sloane's A002787). The number $a(n)$ of semigroups having n IDEMPOTENTS are 1, 2, 6, 26, 135, 875, ... (Sloane's A002788).

Semi-Integral

A FRACTIONAL INTEGRAL of order 1/2. The semi-integral of t^λ is given by

$$D^{-1/2}t^\lambda = \frac{t^{\lambda+1/2}\Gamma(\lambda+1)}{\Gamma\left(\lambda+\frac{3}{2}\right)},$$

so the semi-integral of the CONSTANT FUNCTION $f(t)=c$ is given by

$$D^{-1/2}c = c\lim_{\lambda\to 0}\frac{t^{\lambda+1/2}\Gamma(\lambda+1)}{\Gamma\left(\lambda+\frac{3}{2}\right)} = 2c\sqrt{\frac{t}{\pi}}.$$

Semilatus Rectum

In general, the CHORD through a FOCUS parallel to the DIRECTRIX of a CONIC SECTION is called the LATUS RECTUM. Half this length is called the semilatus rectum (Coxeter 1969).

Given an ELLIPSE, the semilatus rectum is the distance L measured from a FOCUS such that

$$\frac{1}{L} \equiv \frac{1}{2}\left(\frac{1}{r_+}+\frac{1}{r_-}\right), \tag{1}$$

where $r_+ = a(1+e)$ and $r_- = a(1-e)$ are the APOAPSIS and PERIAPSIS, and e is the ELLIPSE's ECCENTRICITY. Plugging in for r_+ and r_- then gives

$$\frac{1}{L} = \frac{1}{2a}\left(\frac{1}{1-e}+\frac{1}{1+e}\right) = \frac{1}{2a}\,\frac{(1+e)+(1-e)}{1-e^2}$$
$$= \frac{1}{a}\,\frac{1}{1-e^2}, \tag{2}$$

so

$$L = a\left(1-e^2\right). \tag{3}$$

Semimagic Square

A square that fails to be a MAGIC SQUARE only because one or both of the main diagonal sums do not equal the MAGIC CONSTANT (Kraitchik 1942, p. 143).

See also MAGIC SQUARE

References
Kraitchik, M. *Mathematical Recreations.* New York: W. W. Norton, 1942.

Semimajor Axis

HALF the distance across an ELLIPSE along the longest of its three principal axes.

See also ELLIPSE, SEMIMINOR AXIS

Semiminor Axis

Half the distance across an ELLIPSE along its short principal axis.

See also ELLIPSE, SEMIMAJOR AXIS

Seminorm

A seminorm is a function on a VECTOR SPACE V, denoted $\|v\|$, such that the following conditions hold for all v and w in V, and any scalar c.

1. $\|v\| \geq 0.$,
2. $\|cv\| = |c|\ \|v\|$, and
3. $\|v+w\| \leq \|v\| + \|w\|$.

Note that it is possible for $\|v\|=0$ for nonzero v. For example, the FUNCTIONAL $\|f\| = |f(0)|$ for continuous functions is a seminorm which is not a norm. A seminorm is a norm if $\|v\|=0$ is equivalent to $v=0$.

See also FRÉCHET SPACE, NORM, TOPOLOGICAL VECTOR SPACE

Semiperfect Magic Cube

A semiperfect magic cube, also called an "Andrews cube," is a MAGIC CUBE for which the CROSS SECTION diagonals do not sum to the MAGIC CONSTANT.

See also MAGIC CUBE, PERFECT MAGIC CUBE

References
Gardner, M. "Magic Squares and Cubes." Ch. 17 in *Time Travel and Other Mathematical Bewilderments.* New York: W. H. Freeman, pp. 213–225, 1988.

Semiperfect Number

A number such as $20 = 1+4+5+10$ which is the SUM of some (or all) of its PROPER DIVISORS is called a semiperfect number, or sometimes a pseudoperfect

number (Butske *et al.* 1999). A semiperfect number which is the SUM of *all* its PROPER DIVISORS is called a PERFECT NUMBER. The first few semiperfect numbers are 6, 12, 18, 20, 24, 28, 30, 36, 40, ... (Sloane's A005835). Every multiple of a semiperfect number is semiperfect, as are all numbers $2^m p$ for $m > 1$ and p a PRIME between 2^m and 2^{m+1} (Guy 1994, p. 47).

A semiperfect number cannot be DEFICIENT. Rare ABUNDANT NUMBERS which are not semiperfect are called WEIRD NUMBERS. Semiperfect numbers are sometimes also called pseudoperfect numbers.

See also ABUNDANT NUMBER, DEFICIENT NUMBER, PERFECT NUMBER, PRIMARY PSEUDOPERFECT NUMBER, PRIMITIVE SEMIPERFECT NUMBER, WEIRD NUMBER

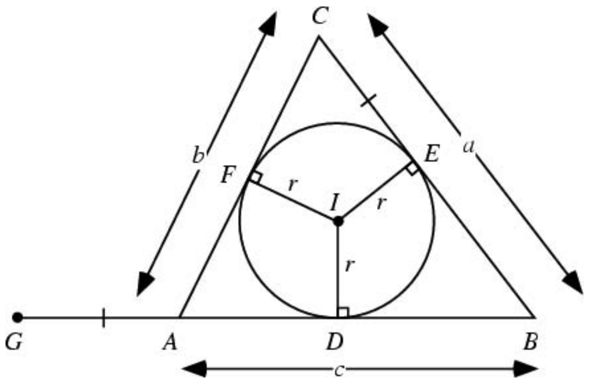
Semiperimeter

The semiperimeter on a figure is defined as

$$s \equiv \tfrac{1}{2} p, \tag{1}$$



where p is the PERIMETER. The semiperimeter of POLYGONS appears in unexpected ways in the computation of their AREAS. The most notable cases are in the ALTITUDE, EXRADIUS, and INRADIUS of a TRIANGLE, the SODDY CIRCLES, HERON'S FORMULA for the AREA of a TRIANGLE in terms of the legs a, b, and c

$$A_\Delta = \sqrt{s(s-a)(s-b)(s-c)}, \tag{2}$$

and BRAHMAGUPTA'S FORMULA for the AREA of a QUADRILATERAL

$$A_{\text{quadrilateral}} = \sqrt{(s-a)(s-b)(s-c)(s-d) - abcd \cos^2\left(\frac{A+B}{2}\right)}. \tag{3}$$

The semiperimeter also appears in the beautiful L'HUILIER'S THEOREM about SPHERICAL TRIANGLES.

For a TRIANGLE, the following identities hold,

$$s - a = \tfrac{1}{2}(-a + b + c) \tag{4}$$

$$s - b = \tfrac{1}{2}(+a - b + c) \tag{5}$$

$$s - c = \tfrac{1}{2}(+a + b - c). \tag{6}$$

Now consider the above figure. Let I be the INCENTER of the TRIANGLE ΔABC, with D, E, and F the tangent points of the INCIRCLE. Extend the line BA with $GA = CE$. Note that the pairs of triangles (ADI, AFI), (BDI, BEI), (CFI, CEI) are congruent. Then

$$\begin{aligned} BG &= BD + AD + AG = BD + AD + CE \\ &= \tfrac{1}{2}(2BD + 2AD + 2CE) \\ &= \tfrac{1}{2}[(BD + BE) + (AD + AF) + (CE + CF)] \\ &= \tfrac{1}{2}[(BD + AD) + (BE + CE) + (AF + CF)] \\ &= \tfrac{1}{2}(AB + BC + AC) = \tfrac{1}{2}(a + b + c) = s. \end{aligned} \tag{7}$$

Furthermore,

$$\begin{aligned} s - a &= BG - BC \\ &= (BD + AD + AG) - (BE + CE) \\ &= (BD + AD + CE) - (BD + CE) = AD \end{aligned} \tag{8}$$

$$\begin{aligned} s - b &= BG - AC \\ &= (BD + AD + AG) - (AF + CF) \\ &= (BD + AD + CE) - (AD + CE) = BD \end{aligned} \tag{9}$$

$$s - c = BG - AB = AG \tag{10}$$

(Dunham 1990). These equations are some of the building blocks of Heron's derivation of HERON'S FORMULA.

See also PERIMETER

References

Semiregular Tessellation

TESSELLATION

Semiring

A semiring is a set together with two BINARY OPERATORS $S(+, *)$ satisfying the following conditions:

1. Additive associativity: For all $a, b, c \in S$, $(a+b)+c = a+(b+c)$,
2. Additive commutativity: For all $a, b \in S$, $a+b = b+a$,
3. Multiplicative associativity: For all $a, b, c \in S$, $(a*b)*c = a*(b*c)$,
4. Left and right distributivity: For all $a, b, c \in S$, $a*(b+c) = (a*b)+(a*c)$ and $(b+c)*a = (b*a)+(c*a)$.

A semiring is therefore a commutative SEMIGROUP under addition and a SEMIGROUP under multiplication. A semiring can be empty.

See also BINARY OPERATOR, RING, RINGOID, SEMIGROUP

Semistable

When a PRIME l divides the DISCRIMINANT of a ELLIPTIC CURVE E, two or all three roots of E become congruent (mod l). An ELLIPTIC CURVE is semistable if, for all such PRIMES l, only two roots become CONGRUENT mod l (with more complicated definitions for $p = 2$ or 3).

See also DISCRIMINANT (ELLIPTIC CURVE), ELLIPTIC CURVE

Sensitivity

The probability that a STATISTICAL TEST will be positive for a true statistic.

See also SPECIFICITY, STATISTICAL TEST, TYPE I ERROR, TYPE II ERROR

Sentence

This entry contributed by MATTHEW SZUDZIK

A sentence is a logic formula in which every variable is QUANTIFIED. The concept of a sentence is important because formulas with variables that are not quantified are ambiguous.

The concept of the sentence can be illustrated as follows (Enderton 1977). The formula $\exists(x, \forall(y, y \in x))$, in which each variable is quantified, can be translated into English as the complete sentence "There exists a set which has every set as an element." However, the formula $\forall(y, (y \in x))$, in which x is not quantified, can only be translated as the sentence fragment "Every set is an element of ___," where "___" is unspecified because x is not quantified.

Because a "quantified variable" is just a more descriptive name for a BOUND VARIABLE, a sentence can also be defined as a logic formula with no FREE VARIABLES.

See also BOUND VARIABLE, FREE VARIABLE, QUANTIFIER, THEORY

Enderton, H. B. *Elements of Set Theory.* New York: Academic Press, 1977.

Sentential Calculus

PROPOSITIONAL CALCULUS

Separating Edge

An EDGE of a GRAPH is separating if a path from a point A to a point B must pass over it. Separating EDGES can therefore be viewed as either bridges or dead ends.

See also EDGE (GRAPH)

Separating Family

A SEPARATING FAMILY is a SET of SUBSETS in which each pair of adjacent elements are found separated, each in one of two disjoint subsets. The 26 letters of the alphabet can be separated by a family of 9,

$$\begin{array}{ccc} (abcdefghi) & (jklmnopqr) & (stuvwxyz) \\ (abcjklstu) & (defmnovwx) & (ghipqryz). \\ (adgjmpsvy) & (behknqtwz) & (cfilorux) \end{array}$$

The minimal size of the separating family for an n-set is 0, 2, 3, 4, 5, 5, 6, 6, 6, 7, 7, 7, ... (Sloane's A007600).

See also KATONA'S PROBLEM

References

Honsberger, R. "Cai Mao-Cheng's Solution to Katona's Problem on Families of Separating Subsets." Ch. 18 in *Mathematical Gems III.* Washington, DC: Math. Assoc. Amer., pp. 224–239, 1985.

Separation

Two distinct point pairs AC and BD separate each other if A, B, C, and D lie on a CIRCLE (or line) in such order that either of the arcs (or the line segment AC) contains one but not both of B and D. In addition, the point pairs separate each other if every CIRCLE through A and C intersects (or coincides with) every CIRCLE through B and D. If the point pairs separate each other, then the symbol $AC//BD$ is used.

Separation of Variables

A method of solving partial differential equations in a function $\Phi(x, y, \ldots)$ and variables x, y, ... by making a substitution OF THE FORM

$$\Phi(x, y, \ldots) \equiv X(x)Y(y)\cdots,$$

breaking the resulting equation into a set of independent ordinary differential equations, solving these for $X(x)$, $Y(y)$, ..., and then plugging them back into the original equation.

This technique works because if the product of functions of independent variables is a constant, each function must separately be a constant. Success requires choice of an appropriate coordinate system and may not be attainable at all depending on the equation. Separation of variables was first used by L'Hospital in 1750. It is especially useful in solving equations arising in mathematical physics, such as

LAPLACE'S EQUATION, the HELMHOLTZ DIFFERENTIAL EQUATION, and the Schrödinger equation.

Separation Theorem

There exist numbers $y_1 < y_2 < \ldots < x_{n-1}$, $a < y_{n-1}$, $y_{n-1} < b$, such that

$$\lambda_v = \alpha(y_v) - \alpha(y_{v-1}).$$

where $v = 1, 2, \ldots, n$, $y_0 = a$ and $y_n = b$. Furthermore, the zeros $x_1, \ldots, x_n$, arranged in increasing order, alternate with the numbers $y_1, \ldots y_{n-1}$, so

$$x_v < y_v < x_{v+1}.$$

More precisely,

$$\alpha(x_v + \epsilon) - \alpha(a) < \alpha(y_v) - \alpha(a) = \lambda_1 + \ldots + \lambda_v < \alpha(x_{v+1} - \epsilon) - \alpha(a)$$

for $v = 1, \ldots, n-1$.

Separatrix

A phase curve (i.e., an invariant MANIFOLD) which meets a HYPERBOLIC FIXED POINT (i.e., an intersection of a stable and an unstable invariant MANIFOLD) or connects the unstable and stable manifolds of a *pair* of hyperbolic or parabolic fixed points. A separatrix marks a boundary between phase curves with different properties.

For example, the separatrix in the equation of motion for the pendulum occurs at the angular momentum where oscillation gives way to rotation. There are also many systems that have pairs of connected fixed points, e.g., the flow in an open cavity, which has a separatrix that connects two parabolic points.

Septendecillion

In the American system, 10^{54}.

Sequence

A sequence is an ordered set of mathematical objects which is denoted using braces. For example, the symbol $\{2n\}_{n=1}^{\infty}$ denotes the infinite sequence of EVEN NUMBERS $\{2, 4, \ldots, 2n, \ldots\}$.

Sequency Function

WALSH FUNCTION

Sequential Graph

A CONNECTED GRAPH having e EDGES is said to be sequential if it is possible to label the nodes i with distinct INTEGERS f_i in $\{0, 1, 2, \ldots, e-1\}$ such that when EDGE ij is labeled $f_i + f_j$, the set of EDGE labels is a block of e consecutive integers (Grace 1983, Gallian 1990). No HARMONIOUS GRAPH is known which cannot also be labeled sequentially.

Series

A series is an (often infinite) sum of terms specified by some rule. If the difference between successive terms is a constant, then the series is said to be an ARITHMETIC SERIES. If each term equals the previous multiplied by a constant, it is said to be a GEOMETRIC SERIES. A series usually has an INFINITE number of terms, but the phrase INFINITE SERIES is sometimes used for emphasis or clarity.

Let the terms in a series be denoted a_i, let the kth partial sum be given by

$$S_k = \sum_{i=1}^{k} a_i \tag{1}$$

and let the sequence of partial sums be given by $\{S_1 = a_1,\ S_2 = a_1 + a_2,\ S_3 = a_1 + a_2 + a_3, \ldots\}$. If the sequence of partial sums does not converge to a LIMIT (e.g., it oscillates or approaches $\pm\infty$), the series is said to diverge. An example of a convergent series is the GEOMETRIC SERIES

$$\sum_{n=0}^{\infty} \left(\tfrac{1}{2}\right)^n = 2. \tag{2}$$

and an example of a divergent series is the HARMONIC SERIES

$$\sum_{n=1}^{\infty} \frac{1}{n} = \infty. \tag{3}$$

A number of methods known as CONVERGENCE TESTS can be used to determine whether a given series converges. Although terms of a series can have either sign, convergence properties can often be computed in the "worst case" of all terms being POSITIVE, and then applied to the particular series at hand. A series of terms a_n is said to be ABSOLUTELY CONVERGENT if the series formed by taking the absolute values of the a_n,

$$\sum_n |a_n|, \tag{4}$$

converges.

An especially strong type of convergence is called UNIFORM CONVERGENCE, and series which are uniformly convergent have particularly "nice" properties. For example, the sum of a UNIFORMLY CONVERGENT series of continuous functions is continuous. A CONVERGENT SERIES can be DIFFERENTIATED term by term, provided that the functions of the series have continuous derivatives and that the series of DERIVATIVES is UNIFORMLY CONVERGENT. Finally, a UNIFORMLY CONVERGENT series of continuous functions can be INTEGRATED term by term.

For a table listing the COEFFICIENTS for various series operations, see Abramowitz and Stegun (1972, p. 15).

While it can be difficult to calculate analytical expressions for arbitrary convergent infinite series,

many algorithms can handle a variety of common series types. The program *Mathematica* implements many of these algorithms. General techniques also exist for computing the numerical values of any but the most pathological series (Braden 1992).

Ramanujan found the interesting series identity

$$1-\frac{3!}{(1!2!)^3}x^2+\frac{6!}{(2!4!)^3}x^4-\cdots$$
$$=\left[1+\frac{x}{(1!)^3}+\frac{x^2}{(2!)^3}+\ldots\right]\left[1-\frac{x}{(1!)^3}+\frac{x^2}{(2!)^3}-\ldots\right] \quad (5)$$

(Preece 1928; Hardy 1999, p. 7).

Series Expansion

This entry contributed by DANIEL SCOTT UZNANSKI

A series expansion is a representation of a particular function as a sum of powers in one of its variables, or by a sum of powers of another (usually elementary) function $f(x)$.

See also LAURENT SERIES, MACLAURIN SERIES, POWER SERIES, SERIES, SERIES REVERSION, TAYLOR SERIES

Series Inversion

SERIES REVERSION

Series Multisection

If

$$f(x)=f_0+f_1x+f_2x^2+\ldots+f_nx^n+\ldots$$

then

$$S(n,\ j)=f_jx^j+f_{j+n}x^{j+n}+f_{j+2n}x^{j+2n}+\ldots$$

is given by

$$S(n,\ j)=\frac{1}{n}\sum_{t=0}^{n-1} w^{-jt}f(w^t x),$$

where $w=e^{2\pi i/n}$.

Series Reversion

Series reversion is the computation of the COEFFICIENTS of the inverse function given those of the forward function. For a function expressed in a series as

$$y=a_1x+a_2x^2+a_3x^3+\ldots, \quad (1)$$

the series expansion of the inverse series is given by

$$x=A_1y+A_2y^2+A_3y^3+\ldots \quad (2)$$

By plugging (2) into (1), the following equation is obtained

$$y=a_1A_1y+(a_2A_1^2+a_1A_2)y^2$$
$$+(a_3A_1^3+2a_2A_1A_2+a_1A_3)y^3$$
$$+(3a_3A_1^2A_2+a_2A_2^2+a_2A_1A_3)+\ldots \quad (3)$$

Equating COEFFICIENTS then gives

$$A_1 = a_1^{-1} \quad (4)$$

$$A_2 = -\frac{a_2}{a_1} A_1^2 = -a_1^{-3} a_2 \quad (5)$$

$$A_3 = a_1^{-5}(2a_2^2 - a_1 a_3) \quad (6)$$

$$A_4 = a_1^{-7}(5a_1 a_2 a_3 - a_1^2 a_4 - 5a_2^3) \quad (7)$$

$$A_5 = a_1^{-9}(6a_1^2 a_2 a_4 + 3a_1^2 a_2 a_3 + 14a_2^4 - a_1^3 a_5 - 21 a_1 a_2^2 a_3) \quad (8)$$

$$A_6 = a_1^{-11}(7a_1^3 a_2 a_5 + 7a_1^3 a_3 a_4 + 84 a_1 a_2^3 a_3 - a_1^4 a_6 - 28 a_1^2 a_2 a_3^2 - 42 a_2^5 - 28 a_1^2 a_2^2 a_4) \quad (9)$$

$$A_7 = a_1^{-13}(8a_1^4 a_2 a_6 + 8a_1^4 a_3 a_4 + 4a_1^4 a_4^2) + 120 a_1^2 a_2^3 4_4 + 180 a_1^2 a_2^2 a_3^2 + 132 a_2^6 - a_1^5 a_7 - 36 a_1^3 a_2^2 a_5 - 72 a_1^3 a_2 a_3 a_4 - 12 a_1^3 a_3^3 - 330 a_1 a_2^4 a_3) \quad (10)$$

(Dwight 1961, Abramowitz and Stegun 1972, p. 16). A derivation of the explicit formula for the nth term is given by Morse and Feshbach (1953),

$$A_n = \frac{1}{n a_1^n} \sum_{s,\,t,\,u\ldots} (-1)^{s+t+u+\ldots} \times \frac{n(n+1)\cdots(n-1+s+t+u\ldots)}{s!t!u!\cdots} \left(\frac{a_2}{a_1}\right)^s \left(\frac{a_3}{a_1}\right)^t \cdots, \quad (11)$$

where

$$s + 2t + 3u + \ldots = n - 1. \quad (12)$$

Series-Reduced Tree

A TREE in which all nodes have degree other than 2 (in other words, no node merely allows a single edge to "pass through"). Series-reduced trees are also called homeomorphically irreducible or topological trees (Bergeron *et al.* 1998). The numbers of series-reduced trees with 1, 2, ... nodes are 1, 1, 0, 1, 1, 2, 2, 4, 5, 10, 14, ... (Sloane's A000014).

The numbers of series-reduced PLANTED TREES are 0, 1, 0, 1, 1, 2, 3, 6, 10, 19, 35, ... (Sloane's A001678). The numbers of series-reduced ROOTED TREES are 1, 1, 0, 2, 2, 4, 6, 12, 20, 39, 71, ... (Sloane's A001679).

Serpentine Curve

A curve named and studied by Newton in 1701 and contained in his classification of CUBIC CURVES. It had been studied earlier by L'Hospital and Huygens in 1692 (MacTutor Archive).

The curve is given by the CARTESIAN equation

$$y(x) = \frac{abx}{x^2 + a^2} \quad (1)$$

and PARAMETRIC EQUATIONS

$$x(t) = a \cot t \quad (2)$$

$$y(t) = b \sin t \cos t. \quad (3)$$

The curve has a MAXIMUM at $x = a$ and a MINIMUM at $x = -a$, where

$$y'(x) = \frac{ab(a-x)(a+x)}{(a^2+x^2)^2} = 0, \quad (4)$$

and inflection points at $x = \pm\sqrt{3}a$, where

$$y''(x) = \frac{2abx(x^2 - 3a^2)}{(x^2 + a^2)^3} = 0. \qquad (5)$$

The CURVATURE is given by

$$\kappa(x) = \frac{2abx(x^2 - 3a^2)}{(x^2 + a^2)^3 \left[1 + \frac{(a^3 b - abx^2)^2}{(x^2 + a^2)^4}\right]^{3/2}} \qquad (6)$$

$$\kappa(t) = \frac{4\sqrt{2}ab[2\cos(2t) - 1]\cot t \csc^2 t}{\{b^2[1 + \cos(4t)] + 2a^2 \csc^4 t\}^{3/2}}. \qquad (7)$$

Serret-Frenet Formulas

FRENET FORMULAS

Set

A set is a FINITE or INFINITE collection of objects in which order has no significance, and multiplicity is generally also ignored (unlike a LIST or MULTISET). Older words for set include AGGREGATE and CLASS. Russell also uses the unfortunate term MANIFOLD to refer to a set. The study of sets and their properties is the object of SET THEORY.

Historically, a single horizontal overbar was used to denote a set stripped of any structure besides order, and hence to represent the order type of the set. A double overbar indicated stripping the order from the set and hence represented the cardinal number of the set. This practice was begun by SET THEORY founder Georg Cantor.

Symbols used to operate on sets include $\cap$ (which means "and" or INTERSECTION), and $\cup$ (which means "or" or UNION). The symbol $\emptyset$ is used to denote the set containing no elements, called the EMPTY SET.

The NOTATION A^B, where A and B are arbitrary sets, is used to denote the set of MAPS from B to A. For example, an element of $X^{\mathbb{N}}$ would be a MAP from the NATURAL NUMBERS $\mathbb{N}$ to the set X. Call such a function f, then $f(1)$, $f(2)$, etc., are elements of X, so call them x_1, x_2, etc. This now looks like a SEQUENCE of elements of X, so sequences are really just functions from $\mathbb{N}$ to X. This NOTATION is standard in mathematics and is frequently used in symbolic dynamics to denote sequence spaces.

Let E, F, and G be sets. Then operation on these sets using the $\cap$ and $\cup$ operators is COMMUTATIVE

$$E \cap F = F \cap E \qquad (1)$$

$$E \cup F = F \cup E. \qquad (2)$$

ASSOCIATIVE

$$(E \cap F) \cap G = E \cap (F \cap G) \qquad (3)$$

$$(E \cup F) \cup G = E \cup (F \cup G). \qquad (4)$$

and DISTRIBUTIVE

$$(E \cap F) \cup G = (E \cup G) \cap (F \cup G) \qquad (5)$$

$$(E \cup F) \cap G = (E \cap G) \cup (F \cap G). \qquad (6)$$

More generally, we have the infinite distributive laws

$$A \cap \left(\bigcup_{\lambda \in \Lambda} B_\lambda \right) = \bigcup_{\lambda \in \Lambda} (A \cap B_\lambda) \qquad (7)$$

$$A \cup \left(\bigcap_{\lambda \in \Lambda} B_\lambda \right) = \bigcap_{\lambda \in \Lambda} (A \cup B_\lambda) \qquad (8)$$

where λ runs through any INDEX SET Λ. The proofs follow trivially from the definitions of union and intersection.

Many classes of sets are denoted using DOUBLE-STRUCK characters. The table below gives symbols for some common sets in mathematics.

symbol	set
$\mathbb{A}$	ALGEBRAIC NUMBERS
$\mathbb{B}$	BOOLEANS
$\mathbb{B}^n$	n-BALL
$\mathbb{C}$	COMPLEX NUMBERS
C^n, $C^{(n)}$	n-differentiable functions
$\mathbb{D}^n$	n-DISK
$\mathbb{H}$	QUATERNIONS
$\mathbb{I}$	INTEGERS
$\mathbb{N}$	NATURAL NUMBERS
$\mathbb{O}$	CAYLEY NUMBERS
$\mathbb{P}$	PRIME NUMBERS
$\mathbb{Q}$	RATIONAL NUMBERS
$\mathbb{R}^n$	real n-tuples
$\mathbb{R}^{m \times n}$	real $m \times n$ matrices

$\mathbb{S}^n$	n-SPHERE
$\mathbb{T}^n$	n-torus
$\mathbb{Z}$	INTEGERS
$\mathbb{Z}_n$	integers (mod n)
$\mathbb{Z}^-$	NEGATIVE INTEGERS
$\mathbb{Z}^+$	POSITIVE INTEGERS
$\mathbb{Z}^*$	NONNEGATIVE INTEGERS

Set Difference

The set difference $A\backslash B$ is defined by

$$A\backslash B = \{x : x \in A \text{ and } x \notin B\}.$$

The set difference is therefore equivalent to the COMPLEMENT SET, and is implemented in *Mathematica* as `Complement`[A, B].

Note that the symbol \ is also used to denote QUOTIENT GROUPS. The symbol $A-B$ is sometimes also used to denote a set difference (Smith *et al.* 1997, p. 68).

Set Direct Product

CARTESIAN PRODUCT

Set Partition

A set partition of a SET S is a collection of disjoint SUBSETS of S whose UNION is S. The number of partitions of the SET $\{k\}_{k=1}^n$ is called a BELL NUMBER.

See also BELL NUMBER, BLOCK, PARTITION, RESTRICTED GROWTH STRING, STIRLING NUMBER OF THE SECOND KIND

Set Theory

The mathematical theory of SETS. Set theory is closely associated with the branch of mathematics known as LOGIC.

There are a number of different versions of set theory, each with its own rules and AXIOMS. In order of increasing CONSISTENCY STRENGTH, several versions of set theory include PEANO ARITHMETIC (ordinary ALGEBRA), second-order arithmetic (ANALYSIS), ZERMELO-FRAENKEL SET THEORY, Mahlo, weakly compact, hyper-Mahlo, ineffable, measurable, Ramsey, supercompact, huge, and n-huge set theory.

See also ANALYSIS (LOGIC), AXIOMATIC SET THEORY, CONSISTENCY STRENGTH, CONTINUUM HYPOTHESIS, DESCRIPTIVE SET THEORY, IMPREDICATIVE, KURATOWSKI'S CLOSURE-COMPONENT PROBLEM, NAIVE SET THEORY, PEANO ARITHMETIC, SENTENCE, SET, THEORY, ZERMELO-FRAENKEL AXIOMS, ZERMELO-FRAENKEL SET THEORY, ZERMELO SET THEORY

Seven Circles Theorem

Draw an initial circle, and arrange six circles tangent to it such that they touch both the original circle and their two neighbors. Then the three lines joining opposite points of tangency are concurrent in a point. The figures above show several possible configurations (Evelyn *et al.* 1974, pp. 31–37).

Letting the radii of three of the circles approach infinity turns three of the circles into the straight sides of a triangle and the central circle into the triangle's incircle. As illustrated above, the three lines connecting opposite points of tangency (with those along the triangle edges corresponding to the vertices of the contact triangle) concur (Evelyn *et al.* 1974, pp. 39 and 42).

Sexy Primes

Since a PRIME NUMBER cannot be divisible by 2 or 3, it must be true that, for a PRIME p, $p \equiv 1,\ 5 \pmod 6$. This motivates the definition of sexy primes as a pair of primes $(p,\ q)$ such that $p-q=6$ ("sexy" since "sex" is the Latin word for "six."). The first few sexy prime pairs are (5, 11), (7, 13), (11, 17), (13, 19), (17, 23), (23, 29), (31, 37), (37, 43), (41, 47), (47, 53), ... (Sloane's A023201 and A046117).

Sexy constellations also exist. The first few sexy triplets (i.e., numbers such that each of $(p,\ p+6,\ p+12)$ is PRIME but $p+18$ is *not* PRIME) are (7, 13, 19), (17, 23, 29), (31, 37, 43), (47, 53, 59), ... (Sloane's A046118, A046119, and A046120). The first few sexy quadruplets are (11, 17, 23, 29), (41, 47, 53, 59), (61, 67, 73, 79), (251, 257, 263, 269), ... (Sloane's A046121, A046122, A046123, and A046124). Sexy quadruplets can only begin with a PRIME ending in a "1." There is only a single sexy quintuplet, (5, 11, 17, 23, 29), since every fifth number of the form $6n \pm 1$ is divisible by 5, and therefore cannot be PRIME.

Shah Function

$$\mathrm{III}(x) \equiv \sum_{n=-\infty}^{\infty} \delta(x-n) \tag{1}$$

where $\delta(x)$ is the DELTA FUNCTION, so $\mathrm{III}(x)=0$ for $x \notin \mathbb{Z}$ (i.e., x not an INTEGER). The shah function is also called the sampling symbol or replicating symbol (Bracewell 1999, p. 77) and obeys the identities

$$\mathrm{III}(ax) = \frac{1}{|a|} \sum_{n=-\infty}^{\infty} \delta\left(x-\frac{n}{a}\right) \tag{2}$$

$$\mathrm{III}(-x) = \mathrm{III}(x) \tag{3}$$

$$\mathrm{III}(x+n) = \mathrm{III}(x) \tag{4}$$

$$\mathrm{III}\left(x-\tfrac{1}{2}\right) = \mathrm{III}\left(x+\tfrac{1}{2}\right). \tag{5}$$

The shah function is normalized so that

$$\int_{n-1/2}^{n+1/2} \mathrm{III}(x)\,dx = 1. \tag{6}$$

The "sampling property" is

$$\mathrm{III}(x) f(x) = \sum_{n=-\infty}^{\infty} f(n)\delta(x-n) \tag{7}$$

and the "replicating property" is

$$\mathrm{III}(x) * f(x) = \sum_{n=-\infty}^{\infty} f(x-n). \tag{8}$$

where $*$ denotes CONVOLUTION.

The 2-D sampling function, sometimes called the bed-of-nails function, is given by

$${}^2\mathrm{III}(x, y) = \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} \delta(x-m, y-n), \tag{9}$$

which can be adjusted using a series of weighted as

$$v(x, y) = \sum R_{mn} T_{mn} D_{mn} \delta(x-m_n, y-n), \tag{10}$$

where R_{mn} is a reliability weight, D_{mn} is a density weight (WEIGHTING FUNCTION), and T_{mn} is a taper. The 2-D shah function satisfies

$${}^2\mathrm{III}(x, y) = \mathrm{III}(x)\mathrm{III}(y) \tag{11}$$

(Bracewell 1999, p. 85).

Shallit Constant

Define $f(x_1, x_2, \ldots, x_n)$ with x_i POSITIVE as

$$f(x_1, x_2, \ldots, x_n) \equiv \sum_{i=1}^{n} x_i + \sum_{1 \le i \le k \le n} \prod_{j=1}^{k} \frac{1}{x_j}.$$

Then

$$\min f = 3n - C + o(1)$$

as n increases, where the Shallit constant is

$$C = 1.369451403937\ldots$$

(Shallit 1995). In their solution, Grosjean and De Meyer (quoted in Shallit 1995) reduced the complexity of the problem.

Casti, J. L. "The Shannon Coding Theorem." Ch. 1 in *Five More Golden Rules: Knots, Codes, Chaos, and Other Great Theories of 20th-Century Mathematics.* New York: Wiley, pp. 207–254, 2000.

Shape Number

FIGURATE NUMBER

Shape Operator

The negative derivative

$$S(\mathbf{v}) = -D_{\mathbf{v}}\mathbf{N} \tag{1}$$

of the unit normal $\mathbf{N}$ vector field of a SURFACE is called the shape operator (or WEINGARTEN MAP or SECOND FUNDAMENTAL TENSOR). The shape operator S is an EXTRINSIC CURVATURE, and the GAUSSIAN CURVATURE is given by the DETERMINANT of S. If $\mathbf{x}: U \to \mathbb{R}^3$ is a REGULAR PATCH, then

$$S(\mathbf{x}_u) = -\mathbf{N}_u \tag{2}$$

$$S(\mathbf{x}_v) = -\mathbf{N}_v. \tag{3}$$

At each point $\mathbf{p}$ on a REGULAR SURFACE $M \subset \mathbb{R}^3$, the shape operator is a linear map

$$S: M_{\mathbf{p}} \to M_{\mathbf{p}}. \tag{4}$$

The shape operator for a surface is given by the WEINGARTEN EQUATIONS.

See also CURVATURE, FUNDAMENTAL FORMS, WEINGARTEN EQUATIONS

Shapiro's Cyclic Sum Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Consider the sum

$$f_n(x_1, x_2, \ldots, x_n) = \frac{x_1}{x_2 + x_3} + \frac{x_2}{x_3 + x_4} + \ldots + \frac{x_{n-1}}{x_n + x_1} + \frac{x_n}{x_1 + x_2}, \quad (1)$$

where the x_js are NONNEGATIVE and the DENOMINATORS are POSITIVE. Shapiro (1954) asked if

$$f_n(x_1, x_2, \ldots, x_n) \geq \tfrac{1}{2} n \quad (2)$$

for all n. It turns out (Mitrinovic *et al.* 1993) that this INEQUALITY is true for all EVEN $n \leq 12$ and ODD $n \leq 23$. Ranikin (1958) proved that for

$$f(n) = \inf_{x \geq 0} f_n(x_1, x_2, \ldots, x_n), \quad (3)$$

$$\lambda = \lim_{n \to \infty} \frac{f(n)}{n} = \inf_{n \geq 1} \frac{f(n)}{n} < \tfrac{1}{2} - 7 \times 10^{-8}. \quad (4)$$

λ can be computed by letting $\phi(x)$ be the CONVEX HULL of the functions

$$y_1 = e^{-x} \quad (5)$$

$$y_2 = \frac{2}{e^x + e^{x/2}}. \quad (6)$$

Then

$$\lambda = \tfrac{1}{2} \phi(0) = 0.4945668\ldots \quad (7)$$

(Drinfeljd 1971).

A modified sum was considered by Elbert (1973):

$$g_n(x_1, x_1, \ldots, x_n) = \frac{x_1 + x_3}{x_1 + x_2} + \frac{x_2 + x_4}{x_2 + x_3} + \ldots + \frac{x_{x-1} + x_1}{x_{n-1} + x_n} + \frac{x_n + x_2}{x_n + x_1}. \quad (8)$$

Consider

$$\mu = \lim_{n \to \infty} \frac{g(n)}{n}, \quad (9)$$

where

$$g(n) = \inf_{x \geq 0} g_n(x_1, x_2, \ldots, x_n), \quad (10)$$

and let $\psi(x)$ be the CONVEX HULL of

$$y_1 = \tfrac{1}{2}(1 + e^x) \quad (11)$$

$$y_2 = \frac{1 + e^x}{1 + e^{x/2}}. \quad (12)$$

Then

$$\mu = \psi(0) = 0.978012\ldots. \quad (13)$$

See also CONVEX HULL

Sharing Problem

A problem also known as the POINTS PROBLEM or UNFINISHED GAME. Consider a tournament involving k players playing the same game repetitively. Each game has a single winner, and denote the number of games won by player i at some juncture w_i. The games are independent, and the probability of the ith player winning a game is p_i. The tournament is specified to continue until one player has won n games. If the tournament is discontinued before any player has won n games so that $w_i < n$ for $i = 1, \ldots, k$, how should the prize money be shared in order to distribute it proportionally to the players' chances of winning?

For player i, call the number of games left to win $r_i \equiv n - w_i > 0$ the "quota." For two players, let $p \equiv p_1$ and $q \equiv p_2 = 1 - p$ be the probabilities of winning a single game, and $a \equiv r_1 = n - w_1$ and $b \equiv r_2 = n - w_2$ be the number of games needed for each player to win the tournament. Then the stakes should be divided in the ratio $m : n$, where

$$m = p^a \left[1 + \frac{a}{1} q + \frac{a(a+1)}{2!} q^2 + \ldots + \frac{a(a+1)\cdots(a+b-2)}{(b-1)!} q^{b-1}\right] \quad (1)$$

$$n = q^b \left[1 + \frac{b}{1} p + \frac{b(b+1)}{2!} p^2 + \ldots + \frac{b(b+1)\cdots(b+a-2)}{(a-1)!} p^{a-1}\right] \quad (2)$$

(Kraitchik 1942).

If i players have equal probability of winning ("cell probability"), then the chance of player i winning for quotas $r_1, \ldots, r_k$ is

$$W_i = D_1^{k-1}(r_1, \ldots, r_{i-1}, r_{i+1}, \ldots, r_k; r_i). \quad (3)$$

where D is the DIRICHLET INTEGRAL of type 2D. Similarly, the chance of player i losing is

$$L_i = C_1^{k-1}(r_1, \ldots, r_{i-1}, r_{i+1}, \ldots, r_k; r_i), \quad (4)$$

where C is the DIRICHLET INTEGRAL of type 2C. If the cell quotas are not equal, the general Dirichlet integral D_n must be used, where

$$a_i = \frac{p_i}{1 - \sum_{i=1}^{k-1} p_i}. \qquad (5)$$

If $r_i = r$ and $a_i = 1$, then W_i and L_i reduce to $1/k$ as they must. Let $P(r_1, \ldots, r_k)$ be the joint probability that the players would be RANKED in the order of the r_is in the argument list if the contest were completed. For $k = 3$,

$$P(r_1, r_2, r_3) = CD_1^{(1,1)}(r_1, r_2, r_3). \qquad (6)$$

For $k = 4$ with quota vector $\mathbf{r} = (r_1, r_2, r_3, r_4)$ and $\Delta = p_2 + p_3 + p_4$,

$$P(\mathbf{r}) = \sum_{i=0}^{r_3-1} \sum_{j=0}^{r_4-1} \binom{r_2 - 1 + i + j}{r_2 - 1,\ i,\ j} \left(\frac{p_2}{\Delta}\right)^{r_2} \left(\frac{p_3}{\Delta}\right)^{i} \left(\frac{p_4}{\Delta}\right)^{j}$$
$$\times C_{p1/\Delta}^{(1)}(r_1, r_2 + i + j) D_{p4/p3}^{(1)}(r_4 - j, r_3 - i). \qquad (7)$$

An expression for $k = 5$ is given by Sobel and Frankowski (1994, p. 838).
